The Mediterranean corn borer, Sesamianonagrioides, is a noctuid that feeds on maize, sugar cane and sorghum in North Africa and Southern Europe. Larvae reared under long day conditions pupate after 5 or 6 larval instars, whereas under short day conditions enters diapause and undergo up to 12 molts before dying or pupating. The role of the brain on the diapause induction is not still clear enough as debrained developed larvae displays several extra larval molts and maintain a noticeable titer of juvenile hormone in their hemolymph. To better understand the mechanism of larval development and diapause we identified proteins with different expression between diapausing and non diapausing larvae. Two- dimensional gel electrophoresis was employed to analyze the protein patterns of the brain of the sixth instar larvae, 2 or 7 days after molt. The spots showing differential expression were analyzed by mass spectrometry (MALDI-TOF MS or MALDI-TOF/TOF MS/MS). This study shows a large number of functionally proteins families in the brain of S. nonagrioides. The proteins expression at the brain in a specific time suggests that different developmental stages need specific proteins to be involved in.

Molecular cloning and analysis of a novel beta-1,3-glucan recognition protein from the ghost moth, *Thitarodes pui* (Lepidoptera, Hepialidae)

Wenjing Wu[1], Zixuan Sun[2], Min Zhang[3], Chao Song[4], Guren Zhang[5]

[1]Sun Yat-sen University, China, [2]Sun Yat-sen University, China, [3]Sun Yat-sen University, China, [4]Sun Yat-sen University, China, [5]Sun Yat-sen University, China

Detection of pathogen surface molecules is the crucial first step of host defense reactions. Beta-1,3-glucan recognition proteins (βGRPs) are soluble pattern recognition proteins that bind to β-1,3-glucans from fungi cell walls and initiate immune responses in insects. A novel βGRP gene was cloned from the ghost moth Thitarodes pui, narrowly distributed at an altitude of 4,100 to 4,650 m in the Mt. Sejila of the Tibetan Plateau. The βGRP was classified into βGRP clade 4 in phylogenetic analysis and designated TpβGRPc. The full-length TpβGRPc cDNA (1,915 bp) has a 1,464 bp open reading frame encoding a protein of 488 amino acid residues including a 21 amino acid residues signal peptide, a 127 bp 5' untranslated region (UTR) and a 324 bp untranslated region in the 3' UTR with a 26 bp polyA tail. The calculated molecular mass of the mature protein is 52,596 Da with an estimated pI of 6.06. Tertiary structure of TpβGRPc contains two distinct regions. The N-terminal domain responsible for β-1,3-glucan binding affinity includes ten putative β-strands. The C-terminal domain shows a classical sandwich-like β-jelly roll fold that is similar to β-1,3-glucanases. In phylogenetic tree, TpβGRPs (TpβGRPa, TpβGRPb and TpβGRPc) formed a distinct and separate clade 4 in Lepidopteran βGRP family, which might ascribe to the local distribution of the homoneurous primitive ghost moth.

The cabbage moth modulates the adult eclosion time in response to the amplitude of temperature cycle

Kazuhiro Tanaka[1], Yasuhiko Watari[2]

[1]Miyagi Gakuin Women's University, Japan, [2]Ashiya University, Japan

Adult eclosion rhythm of the cabbage moth, Mamestra brassicae, pupating in the soil, was recorded in darkness under two thermoperiods, 24°C (12h):16°C (12h) and 20.5°C (12h):19.5°C (12h), with different amplitude and the same average temperature. Clear daily rhythms of eclosion were observed in both conditions. However, moths eclosed about 2h before the tempeture drop in 20.5°C:19.5°C, but 4h later in 24°C:16°C. This response to the amplitude of temperature cycle, together with similar previous observations of adult eclosion rhythms in dipterous insects, might suggest a widespread means of adaptation among insects pupating in the soil to compensate for the depth-dependent phase delay of the temperature cycle that is the only time cue available in the soil.

Effects of knockdown of the adipokinetic hormone receptor on nutritional levels and feeding frequency in the two-spotted cricket *Gryllus bimaculatus*

Takahiro Konuma[1], Nobukatsu Morooka[2], Hiromichi Nagasawa[3], Shinji Nagata[4]

[1]The University of Tokyo, Japan, [2]The University of Tokyo, Japan, [3]The University of Tokyo, Japan, [4]The University of Tokyo, Japan

Adipokinetic hormone (AKH) is a crucial peptide hormone in insects that modulates the nutritional homeostasis by mobilizing lipid and carbohydrate. In this presentation, to address how imbalanced nutrientional levels in hemolymph would influence feeding behavior, we manipulated the expression level of AKH receptor in the two-spotted cricket, Gryllus bimaculatus. First, we cloned a cDNA encoding the receptor for AKH in this species (GrybiAKHR). Ca-imaging using Hek293 cells expressing GrybiAKHR confirmed that GrybiAKHR functions as an AKHR. Next, we performed phynotypic analyses using AKHR-downregulated crickets by RNA interference (RNAi) targeting GrybiAKHR. Knockdown of GrybiAKHR decreased hemolymph levels of 1, 2-diacylglycerol and trehalose, while it increased the level of triacylglycerol in the fat body, probably due to the consequent reduction of AKH signaling. In addition, observation in GrybiAKHR knockdowned crickets revealed three characteristic behavioral changes; (1) enhanced starvation resistance, (2) decreased locomotor activity, and (3) increased feeding frequency without changing meal duration. These data led us to a conclusion that the increased feeding frequency in AKHR-knockdowned crickets is affected by decreasing the levels of hemolymph lipid and carbohydrate below a certain threshold for maintenance the continuous nutrient demands. We also concluded that the nutrient levels in hemolymph which are partly controlled by AKH signaling affect feeding behavior, particularly feeding frequency. Trade-off between status of the economized expenditure and the status of the mobilizing energy source from the fat body might take place via AKH-signaling.

Identification and characterization of α-amylase in the gut of Red Palm Weevil, *Rhynchophorus ferrugineus* (Olivier, 1790) (Coleoptera: Curculionidae)

Ali R. Bandani[1], Ali Darvishzadeh[2]

[1]*University of Tehran, Iran,* [2]*University of Tehran, Iran*

The Red Palm Weevil, Rhynchophorus ferrugineus (Oliver) (Coleoptera: Curculionidae), is a serious pest of a wide range of plant species including coconut, sago, date and oil palms. It is native to Middle East countries where it is called Asian Palm Weevil, and it has been widely distributed in Southern Asia. Thus, the aim of the current study was to identify and characterize α-amylase activity to gain a better understanding of digestive physiology of the insect. Thus, the α-amylase in the gut of red palm weevil was isolated and characterized using starch as a substrate. For experiments, last instar larvae were collected from the date fields from Saravan and their gut was removed and homogenized in distilled water. The samples then were centrifuged and their supernatant was separated and kept as an enzyme source. The α-amylase has an optimum pH and temperature of 5 and 40oC, respectively. The activity of α-amylase was increased by NaCl and KCl and inhibited by other compounds such as MgCl2, CaCl2, Urea, EDTA, and SDS. Native-PAGE electrophoresis of α-amylase showed two isoenzymes, one major and one minor band showing α-amylase importance in the carbohydrate metabolism of the insect.

Induced transcription profile of cecropin and defensin gene families in vector mosquito, *Armigeres subalbatus*

Hau-you Tzeng[1], Wen-Chi Chang[2], Chun-Hsien Lin[3], Wu-Chun Tu[4]

[1]National Chung-Hsing University, Taiwan, [2]National Chung-Hsing University, Taiwan, [3]National Chung-Hsing University, Taiwan, [4]National Chung-Hsing University, Taiwan

Cecropins and defensins, well-known antimicrobial peptide gene families, are related to innate immunity in vertebrate and invertebrate. Five cecropin genes, AsCecA1, AsCecA2, AsCecB1, AsCecB2 and AsCecN, and four defensin genes, AsDefA1, AsDefA2, AsDefB and AsDefC, were cloned from Armigeres subalbatus. To understand the induced temporal transcription profiles of cecropin and defensin gene families in Ar. subalbatus, mosquitoes were injected with heat-killed bacteria, Escherichia coli BL21 and Staphylococcus aureus CCRC 15211, respectively, and examined the transcriptional level of cecropin and defensin genes from 10 min to 120 h after treatment with real-time PCR. The results revealed that higher transcriptional level was induced in virgin female mosquitoes treated with heat-killed E. coli than S. aureus. In addition, the AsCecB2 was the only exception that no obvious induction among the cecropin and defensin genes tested. Induced temporal transcription profiles for treatments of E. coli and S. aureus could be divided into three types shown as follows: first, up-regulation at the same time, i.e., AsCecA2, AsCecB1, AsCecN, AsDefA1 and AsDefB; second, up-regulation at different time, i.e., AsDefA2; third, irregular induced transcription profile, i.e., AsCecA1. As mentioned in above, transcriptional regulation of antimicrobial peptide gene families is complicated and further investigation in the future will be needed.

Temperature dependent changes of chemical components in overwintering and non-overwintering predatory ladybird *Hippodamia variegata* (Coleoptera: Coccinellidae)

Nayereh Hamedi[1], Saeid Moharramipour[2], Mohsen Barzegar[3]

[1]Faculty of Agriculture, Tarbiat Modares University, Iran, [2]Faculty of Agriculture, Tarbiat Modares University, Iran, [3]Faculty of Agriculture, Tarbiat Modares University, Iran

Hippodamia variegata (Goeze) is a widespread aphidophagous predator that has been reported as the most important natural enemy of aphids, in many countries. Coccinellids, as many other insect species, minimize low temperature injuries by a series of behavioral and physiological strategies such as seeking shelter, dormancy and accumulating sugars and polyols. Adults of H. variegata cease their reproduction around the middle of October and spend autumn, winter and early spring in altitude of 1800-2200m in aggregations beyond the tore bushy plants. In this study, biochemical parameters were measured in overwintering and non-overwintering adults of H. variegata collected from mountain of Hamadan, Iran and farm from September 2010 to June 2011. The concentrations of cryoprotectants (myo-inositol, trehalose, glycerol and glucose) fluctuated during the study period. Overwintering coccinellids displayed 45 folds higher myo-inositol accumulations compared to non-overwintering insects. However, trehalose, glycerol and glucose contents increased 3 to 6 folds. It was suggested that myo-inositol is the most important cryoprotectants in this species. Large amounts of metabolic reserves in the form of glycogen accumulated prior to overwintering. Glycogen began breakdown and polyols accumulated when ambient temperature decreased from October to December. In the other hands, there was a significant correlation between ambient temperature and glycogen decrease, and myo-inositol, sugar and polyols increase. Findings indicated that low temperatures may induce polyols accumulation in H. variegata.

The effect of four different host plants on digestive proteolytic and amylolytic activity of the cotton bollworm, *Helicoverpa armigera* (Hubner) (Lepidoptera : Noctuidae)

Neda Fallahnejad Mojarrad[1], Yaghoub Fathipour[2], Karim Kamali[3], Bahram Naseri[4]

[1]Science and Research Branch ,Islamic AZad University, Iran, [2]Tarbiat Modares University , Tehran, Iran, [3]Tarbiat Modares University ,Tehran, Iran, [4]Universiyu of Mhaghegh Ardabili ,Ardabili, Iran

The cotton bollworm, Helicoverpa armigera (Hubner) is an important and polyphagous pest worldwide. Digestive proteolytic and amylolytic activity of the larvae of H. armigera fed on different host plants including white kidney bean, (cultivar Dehghan), common bean (cultivar Khomein), red kidney bean (cultivar Goli) and soybean (Williams) was determined. The substrates Azocasein (pH 6 to 12) and starch (pH 2 to 10) were used for assaying proteolytic and amylolytic activity of midgut extracts from H. armigera. The experiments were preformed at 25±1ºC, 65±5% RH and a photoperiod of 16:8 (L: D) h. The results of this study showed that the highest general proteolytic activity of the third, fourth and fifth instar larvae was on Goli (8.89 U/mg), Dehghan (9.08 U/mg) and Dehghan (8.85 U/mg), respectively. In addition, the highest amylolytic activity of the third, fourth and fifth instar larvae was on Goli, Goli and Khomein (0.873, 0.998 and 0.899 U/mg, respectively). Optimum pH of digestive proteolytic and amylolytic activity in the larvae fed on different host plants was observed on Williams (0.011U/mg) probably due to the presence of serine protease inhibitors in this cultivar, resulting in hyperproduryction of chymotrypsin ans tryptic on Williames (0.370 ± 0.03 and 0.303 ±0.03 U/mg, respectively) , in response to the inhibition of the serine proteases. The results indicated that the Dehghan and Williams cultivars were the most suitable and unsuitable hosts to this pests, respectively.

The cotton boll worm, Helicoverpa armigera (Hubner) is a serious pest of different agriculture crops in most parts of the world.The best time for the activity of protease and amylase in the midgut of the larvae of H.armigera was determined at 25±1ºC, 65±5%RH and a photoperiod of 16:8 (L: D) h. The midgut from H.armigera fifth instar larvae reared on chickpea (cultivar Arman) were anatomized and the supernatants were used as the source of enzyme. The substrates of Azocasein and Starch were used for measuring proteolytic and amilolytic activities, respectively. The activity of protease enzymes increased linearly for 20 to 60 minutes from the incubation time. But at the incubation time, it turned 80 minutes toward the linear mode. In addition, the activity of amylase enzyme increased linearly for 20 to 40 minutes from the incubation time. But at the incubation time, it turned 60 minutes toward the linear mode. The results showed that the means of linear part of the absorb time reaction is the appropriate time for the examination of the proteolytic and amilolytic activites. Also, significant relationship between the age of insect and variety on general proteolytic and amylolytic was determined by factorial design between two treatments. The results showed that larval instars and variety have significant effect on general proteolytic and amylolytic activites ($P< 0.01$).

Effect of different host plants on some biochemical characteristics of digestive proteases of *Hellicoverpa armigera* (Lepidoptera: Noctudidae)

Neda Fallahnejad Mojarrad[1], Yaghoub Fathipour[2], Karim Kamali[3], Bahram Naseri[4]

[1]Science and Research Branch ,Islamic AZad University, Iran, [2]Tarbiat Modares University, Iran, [3]Tarbiat Modares University, Iran, [4]University of Mohaghegh Ardabili, Ardabil, Iran

The cotton bollworm, Helicoverpa armigera (Hubner) is one of the serious pests of different economic crops in many parts of the world including Iran. Study of insect digestive enzymes is necessary in order to reach practical and new pest management technologies. The midgut from H. armigera fifth instar larvae reared on artificial diets based on different host plants including common bean (cultivar Khomein), white kidney bean (cultivar Dehghan), red kidney bean (cultivar Goli) and soybean (cultivar Williams) were anatomized, and the supernatants were used as the source of enzyme. The results of zymogram analysis on gel showed that protease enzymes in midgut of the cotton bollworm fed on different host plants had two isoforms. The km valves of 7.830 and 5.390 mm and the Vmax valves of 0.033 and o.016 mmol/min were estimated for trpsin on Williams and Goli, respectively. Also calculated km and Vmax for chymotryipsin were 7.930 and 3.260 mM and 0/057 and 0.028 mmo1/min, respectively. Determining biochemical characteristics of insect digestive enzymes could be useful to reach safe and suitable controlling methods, as well as, to obtain better understanding of the enzymes role in nutritional physiology of the insect pests.

Identification and characterization of α-amylase in the iranian population of the Rose Aphid, *Macrosiphum rosae* (Linnaeus, 1758) (Hemiptera: Aphididae)

Ali Darvishzadeh[1], Ali Moslemi[2], Ali R. Bandani[3]

[1]University of Tehran, Iran, [2]University of Zabol, Iran, [3]University of Tehran, Iran

Aphids are considered a serious agricultural and horticultural pest that causes serious damage to crops by their feeding, and, more importantly, by transmitting various plant viruses to their hosts. In addition, 'honeydew' excreted by the aphids attracts saprophytic fungi which cover the leaves leading to reduction of photosynthetic capacity of the host plant. Rose aphid, M. rosae (Hemiptera: Aphididae), is a cosmopolitan pest that cause severe damage to various members of the Rosaceae. This pest may have various hosts during the year, however, it is most commonly found feeding on roses. The aim of this study was extraction and characterization of α-amylases of M. rosae to get a better understanding of the digestive physiology of this insect species. First one population of aphid was reared on host species. After preparing aphids with the same age, adult insects were collected for further testing. Adult insect (200 numbers) were homogenized and their enzymes were extracted. The activity of digestive α-amylase suing 1% starch as a substrate was determined to be 1.59± 0.0051 Unit. Optimum pH was determined to be 7.0. Optimum temperature was 45oC but the enzyme was active in a wide range of temperature from 20 to 60oC. Zymogram analysis using vertical gel electrophoresis showed that only one amylase band is present in the gel. Thus, these experiments showed that Rose aphid has optimum activity at neutral pH and has only one isozyme.

Evaluation of proteolytic activity in *Rhynchophorus ferrugineus* (Coleoptera: Curculionidae) (Olivier, 1790) and efficiency of synthetic inhibitors in electrophoresis

Ali Darvishzadeh[1], Ali R. Bandani[2]

[1]University of Tehran, Iran, [2]University of Tehran, Iran

Rhynchophorus ferrugineus (Coleoptera: Curculionidae) is an important pest of dates in Iran and Persian Gulf countries. This pest has been observed in Iran for the first time in 1992 from a village in Saravan (Sistan and Baluchestan province) and then its damage has been observed in different places. Thus, the aim of the current study was identification and characterization of the proteolytic activity using general and specific substrates to obtain a better understanding of digestion physiology in the pest. Therefore, the enzymes in the digestive tract of the larvae were isolated and its properties were investigated using the general substrate (Azocasein) and specific substrates of serine proteases. Specific used substrates were Nα-benzoyl-DL-arginine p-nitroanilide (BApNA) for trypsin activity and N-succinyl-alanine-alanine-proline-phenylalanin p-nitroanilidine (SAAPFpNA) for chymotrypsin activity. This study showed that the optimum proteolytic pH activity by using Azocasein substrate increased in both at pH 6 and 10 indicating the existence of two series of enzymes digesting protein (serine and cysteine) in the digestive system of the insect. Further studies using specific substrates at three pHs of 6.0, 8.0 and 10.0 showed that activity of chymotrypsin is more than trypsin and the enzymes activity were increasing in higher pHs in both enzymes. The effect of synthetic inhibitors TLCK, TPCK, PMSF, E64 and SBTI on the proteolytic activity in SDS-Electrophoresis showed that a mixture of the proteolytic enzymes are present in the insect gut.

Characterization of α-amylase in the Italian Locust, *Calliptamus italicus* (Linnaeus 1758), (Orthoptera: Acrididae)

Ali Darvishzadeh[1], Ali Moslemi[2], Ali R. Bandani[3]

[1]University of Tehran, Iran, [2]University of Zabol, Iran, [3]University of Tehran, Iran

Calliptamus italicus L. is a polyphagous insect which is widely distributed throughout of Europe, Middle East and North Africa. Unlike the Moroccan and Desert locusts, C. italicus migrate short distances. In some years, due to changes in weather conditions and dry vegetation, they make damage to the adjacent field crops. Aim of the current study was to investigate α-amylase activity of this insect species. Insects were collected from Tehran province and 10 adult insects were homogenized and their enzymes were extracted. The activity of digestive α-amylase was 0.022± 0.0081 Unit activity. Italian Locust α-amylase activity pH was determined to be around 8.0. The enzyme activity was decreased sharply after pH 9.0, but the enzyme activity steadily increased from pH 3.0 to 9.0. Thus it could be said that the enzyme is more active in acidic region than the alkaline condition. Generally, optimal pH is corresponding to the pH prevailing in the midgut from which the enzyme has been extracted so these discrepancies seen in midgut pH are related to the different feeding habits and feeding sources. The optimal temperature for C. italicus α-amylase activity was 40°C, the enzyme was active over a broad temperature range from 30 to 60°C. Zymogram analysis of this grasshopper by vertical slab gel electrophoresis using starch as substrate showed 9.0 bands of amylase activity indicating extensive amylase activity.

Identification and characterization of α-amylase in citrus swallowtail, *Papilio demoleus* (Linnaeus 1758), (Lepidoptera: Papilionidae)

Ali Darvishzadeh[1], S. Qasem Mousavi[2], Ali R. Bandani[3]

[1]University of Tehran, Iran, [2]University of Tehran, Iran, [3]University of Tehran, Iran

Papilio demoleus L., commonly known as the lime or Citrus Swallowtail that has been distributed in many asian countries. It insect pest has a good potential to be a major pest in India, Pakistan, Iraq and the other Middle East countries. Thus, the aim of the current studies was to investigate α-amylase activity of the insect. So, the last instar larvae were collected from around Surry (Mazandaran Province). Then larvae placed on ice to become motionless and their guts were isolated. After that larvae gut were homogenized in distilled water and centrifuged and supernatant was kept at -20 oC as an enzyme source. This study showed that α-amylase activity was present in the insect larvae in order to digest carbohydrates. Optimum temperature and pH of the α-amylase using starch as substrate were determined to be 45 oC and 8.0, respectively. Enzyme kinetic studies using five different substrate concentrations including 0.05, 0.1, 0.2, 0.4, and 1.0 % and fixed enzyme concentration showed that Vmax and Km were 0.19 U and 0.46 % substrate, respectively. Understanding of the digestive physiology and α-amylase activity of Citrus Swallowtail is important when new management strategies for this economically important pest are devised.

Ecological significance of cooling rates improving the cold hardening of overwintering *Hippodamia variegata* (Coleoptera: Coccinellidae)

Nayereh Hamedi[1], Saeid Moharramipour[2]

[1]*Tarbiat modares university, Iran,* [2]*Tarbiat modares university, Iran*

Hippodamia variegata (Goeze) is an aphid predator used in the biological control of plant lice in cereals and oil plants in diverse countries. Low temperature is the major adverse environmental factor that insects must overcome in temperate and cold regions. Therefore, cold hardiness strategy of overwintering H. variegata, collected from mountains of Hamadan, Iran was studied from October 2010 to April 2011. In order to assess the acute freezing tolerance status of the adult insects, whole body supercooling point (SCP) and the ability to survive at subzero temperatures with two cooling rates of 0.5 and 0.04 °C/min was investigated in each month. This study showed that H.variegata exhibited high SCP with mean seasonal values upper than -10°C. Coccinellids were alive below SCP. The lower lethal temperatures (LLTs) of overwintering adults were approximately 10 and 20°C lower than their SCPs at cooling rates of 0.5 and 0.04 °C/min, respectively, indicating that this species is would be a freezing tolerant insect. These findings suggests ecological importance of low cooling rates as occur naturally in the overwintering sites and enhance the development of cold hardiness. As LLTs of overwintering H. variegata were about 26-45 °C lower than average ambient temperatures, it seems they successfully pass the severe condition of winter in Iran.

The architecture of Sunggau in Bangka Island, Indonesia - An artificial wild honey bee nest

Kila Nurtjahya
Junior High School, Indonesia

Business of honey bee has not positively responded by the people of Bangka Island, even though the production of honey is from forest. The ideal architecture of artificial bee nest (sunggau) needs to be identified in order to increase the successfulness of the forest honey bee to build their nests, and to gain the utmost volume of honey. The sunggau architecture of wild bee (Apis dorsata) in Bangka consists of a piece of log, its average length is 344 cm, diameter 28 cm, front height is 213 cm, rear height is 119 cm, it forms an angle of 19°, opening width is 78 cm, the width of the middle part is 118 cm, the width of the back part is 79 cm, the length of inner area is 181 cm, and its volume is 2.9 m^3. The main log should be dry and / or fresh and it should not be decayed or moldy. Along the edge and the rear of the sunggau are covered by shrub/bush, its diameter +/- 5 cm or by placing pieces of logs, diameter 4 - 6 cm. The directions of the opening of the sunggau can be any, but need a space free from shrub and trees to be the direction of the bees coming in. The frequency of the honey harvest has stronger correlation with angle of sunggau and room volume. Direction and type of wood have no strong correlation.

Behavioural and physiological differences between the Mediterranean fruit fly, *Ceratitis capitata* (Wiedemann) and the Natal fruit fly, *C. rosa* Karsch and how it relates to their distribution

Marelize De Villiers[1], Vaughan Hattingh[2]

[1]Department of Conservation Ecology & Entomology, Stellenbosch University, South Africa, [2]Department of Conservation Ecology & Entomology, Stellenbosch University, South Africa

Ceratitis capitata and C. rosa are serious pests of fruit produced in South Africa. Being of phytosanitary concern, they restrict international fruit trade. A study was conducted to determine how behavioural and physiological differences between these species relate to their South African distribution. Field sampling sites were chosen to represent different climatic regions. At each site, three yellow bucket traps, baited with Biolure® Fruit Fly and dichlorvos to kill the attracted flies, were placed in host trees in back gardens and inspected monthly for two years. Ceratitis rosa adults and pupae are more sensitive to desiccation and pupae less sensitive to immersion in water than C. capitata, suggesting that C. capitata may be better adapted to drier climates, while C. rosa may be better suited to tropical conditions. This was reflected in their South African distribution where C. capitata was widespread, while C. rosa was absent from or less abundant in the drier regions where C. capitata had a high abundance. Along the wetter, moderate south and east coast, C. rosa was the most abundant species. Ceratitis rosa has a crepuscular behaviour and cannot mate if temperatures during the sunset period fall below 17°C. In addition, C. capitata can develop rapid cold hardening after low temperature exposure faster than C. rosa and the response lasts longer, suggesting that C. capitata has an advantage over C. rosa for survival in colder climates. The data suggests that globally, C. rosa does not have the potential to become as widespread as C. capitata.

Physical and chemical stimuli that affects *Dactylopius opuntiae* anchorage

Adriana Perez-Ramirez[1], Federico Castrejon-Ayala[2], Alfredo Jimenez-Perez[3]

[1]Centro de Desarrollo de Productos Bioticos, Mexico, [2]Centro de Desarrollo de Productos Bioticos, Mexico, [3]Centro de Desarrollo de Productos Bioticos, Mexico

The "grana insect complex" is formed by two different species (Dactylopius coccus and D. opuntiae) and it is important in mexican agriculture. D. cocous or "grana fina" is cultivated on nopal (Opuntia ficus.indica) to obtain carminic acid an important mexican export commodity. Nopal plants infested by "grana fina" may live up to 6 or 7 years while infested by D. opuntiae or "grana silvestre" may die in 6 months. The latest also produces carminic acid, but its yield is negligible. Both insects may live in the same region, so producers are aware of the potential invasion. "Grana silvestre" is controlled with chemical pesticides. Little is known about the stimuli involved in host selection and even more, the clues used by nymphs to settle down. Once the insect settles, it won´t move anymore. We tested different physical and chemical treatments to reduce the number of nymphs on the nopal cladodes. Nymphs do not discriminate between basic colors nor lines or dots presented on a white floor. However, nymphs discriminate between basic colors and horizontal lines and dots and a black wall when these stimuli were presented on a wall. Texture is not relevant for nymph anchorage. 50-d after application of an alcoholic dilution of cineol, eugenol, menthol and alcoholic extract of "grana silvestre" the number of nymphs on the cladode was reduced 71, 67 and 63% compared with the control. 107 d after application, cladodes treated with menthol and cineol had 75.7 and 35.45% (respectively) less colonized area than the control.

Effect of weight and age at mating on *Copitarsia decolora* reproductive potential

Maria Magdalena Callado-Galindo[1], Patricia Villa-Ayala[2], Georgina Sanchez-Rivera[3], Alfredo Jimenez-Perez[4]
[1]Centro de Desarrollo de Productos Bioticos, Mexico, [2]Centro de Desarrollo de Productos Bioticos, Mexico, [3]Centro de Desarrollo de Productos Bioticos, Mexico, [4]Centro de Desarrollo de Productos Bioticos, Mexico

The cabbage moth, Copitarsia decolora is an important pest of cruciferous plants in Mexico and it is a quarantine insect for USA. A single larvae may destroy a whole plant. The use of mating disruption tactics requires knowledge on the mating system of the target insect. This abstract reports our findings on the effect of bodysize and age at mating on reproductive performance of this pest. Fecundity and fertility was affected by female and male age at mating and the female weight. Four-d-old females laid significantly more eggs than any other age tested. Females that mated with 2-4-d-old males laid significantly more eggs than those that mated 6-8-d-old males. Similarly, females mated to 2-4-d-old males produced more fertile eggs than those mated to 6-8-d-old-males. The total number of oviposited and fertile eggs/day/female followed a similar trend. Oviposition dynamics were clearly different. Four-d-old females mated to 2-4-d-old males oviposited more than 80% of their total egg load by day 6, while 4-d-old females mated to 6-8-d-old reached similar figure on the 10th day. However, more than 80% of fertile eggs of 4-d-old females mated to 6-8 d-old were laid by day 12. Female fecundity was significantly and positively affected by female weight. Moreover, male weight significantly affected female fertility. Females mated at early age lived less than 8- and 10-d-old females. Female and male weight did not affect insect longevity. Based on our results, mating disruption or any other behavioral control method may be used in an IPM scheme.

Impact of leaf-miner insects on the primary metabolism of their host-plant: Manipulating from the inside

Melanie Body[1], Isabelle Mazerie[2], Jerome Casas[3], Jean-Philippe Chirstides[4], Vincent Burlat[5], Jean-Paul Monge[6], David Giron[7]

[1]Universite Francois Rabelais, France, [2]Universite Francois Rabelais, France, [3]Universite Francois Rabelais, France, [4]Universite Francois Rabelais, France, [5]Universite Paul Sabatier III, France, [6]Universite Francois Rabelais, France, [7]Universite Francois Rabelais, France

Endophytophagous insects, such as stem-boring, gall-forming and leaf-mining insects, live within plant tissues and feed internally. This life-style presumably provides adaptive advantages for the insect over other external-feeding modes by allowing access to most nutritional tissues while avoiding main plant defensive compounds. This selective-feeding behavior can be reinforced by manipulating the plant physiology, as suggested by the formation of 'green-islands' around mining caterpillars in yellow leaves. We study this so-called 'nutrition hypothesis' on the system Malus domestica/Phyllonorycter blancardella. Thanks to colorimetric assays, capillary electrophoresis and GC/MS, we quantified proteins, starch, total soluble carbohydrates, main individual carbohydrates and free amino acids on green and yellow mined leaves. Our results suggest an active manipulation of the plant primary metabolism by the leaf-miners with a plant response to insect herbivory strongly dependent of the feeding mode of the larva. Indeed, this species is characterized by a larval hyper-metamorphosis with first instars being fluid-feeders and last instars being tissue-feeders. Tissue-feeding larvae control their micro-environment in order to generate a microenvironment with all the nutrient supply needed for their growth and survival but fluid-feeding larvae seem to be limited in such capacity to manipulate the plant physiology. All together the observed plant metabolic changes in the mine further strengthen the hypotheses that mines behave independently from the hosting leaf, operating a metabolic machinery on their own. By isolating the mine from the rest of the leaf, the insect buffers environmental variations of plant quality, presumably protects itself from plant defenses and obtain a nutritional autonomy.

Cooperation between *Wolbachia* and leaf-miners to produce "green-islands": Insights into the plant-insect-bacteria interaction

Wilfried Kaiser[1], Elisabeth Huguet[2], Sylvain Guyot[3], Franck Dedeine[4], Florence Gutzwiller[5], Carlos Lopez-Vaamonde[6], Jerome Casas[7], David Giron[8]

[1]Universite Francois Rabelais, France, [2]Universite Francois Rabelais, France, [3]Universite Francois Rabelais, France, [4]Universite Francois Rabelais, France, [5]Universite Francois Rabelais, France, [6]Universite Francois Rabelais, France, [7]Universite Francois Rabelais, France, [8]Universite Francois Rabelais, France

The life-cycles of many organisms are constrained by the seasonality of resources. This is particularly true for leaf-mining herbivorous insects who use deciduous leaves to fuel growth and reproduction even beyond leaf fall. Our results suggest that an intimate association with bacterial endosymbionts might be their way of coping with nutritional constraints to ensure successful development in an otherwise senescent environment. We show that the phytophagous leaf-mining moth Phyllonorycter blancardella (Lepidoptera) relies on bacterial endosymbionts, most likely Wolbachia, to manipulate the physiology of its host plant resulting in the "green-island" phenotype - photosynthetically active green patches in otherwise senescent leaves - and to increase its fitness. Curing leaf-miners of their symbiotic partner resulted in the absence of green-island formation on leaves, increased compensatory larval feeding, and higher insect mortality. Our results suggest that bacteria impact green-island induction through manipulation of cytokinin levels. All individuals analyzed so far are closely associated with Wolbachia and a key enzyme of the cytokinin biosynthetic pathway (ipt: isopentenyl transferase) has been isolated, cloned and sequenced from the Wolbachia genome (tRNA-ipt Wo). This key enzyme is clearly expressed in Wolbachia-infected insects. This is the first example of an insect bacterial endosymbionts associated with alterations of the plant physiology. Our results highlight (i) the intimate interactions between the bacterial symbionts and their insect host and (ii) the presence of cytokinin-producing Wolbachia and associated plant physiological alterations in different population of this species as well as in different plant-leafminer systems.

The role of *Atelocera raptorial* (Hemiptera : Pentatomidae) in the succession of fungal populations within pecan nut (*Carya Illinoensis*) orchards in South Africa

Vaughn Richmond Swart[1], Jaco Saaiman[2], Gert Johannes Marais[3]

[1]University of the Free State, South Africa, [2]University of the Free State, South Africa, [3]University of the Free State, South Africa

Insects harbour and disseminate fungal propagules and may contribute to the occurrence and development of disease within crop production, consequently affecting the yield in terms of quantity, quality and safety. The role of insects in the spread and occurrence of fungal pathogens is not well documented for most crop production systems and no such data exists for the dissemination of fungal pathogens within new crops, e.g. pecan nuts, in South-Africa. The main aim of the study is to follow the succession of the fungi associated with Atelocera raptoria during the seasonal production of pecan nuts; secondly, to compare the occurrence and possible sources of fungal pathogens in different niches such as soil, air and the phylosphere with the fungi associated with A. raptoria. Sampling was conducted at the Vaalharts district at three different times during the growing season of the pecan nuts. One hundred pentatomid specimens, as well as air, soil and leaf samples were taken on three different occasions. Preliminary results indicated that potential pathogens and contaminants from genera such as Alternaria, Aspergillus, Cladosporium, Fusarium and Penicillium were prominent on A. raptoria and in the environment. This study provides relevant information emphasizing the dynamics of insect-fungal associations in nut orchards. Furthermore, it is envisaged that insect-fungal relations could likely be incorporated into a bio-monitoring protocol for fungal communities.

Effect of different environmental conditions on plant defenses mediating interactions between the Mountain Pine Beetle and its host pine trees

Inka Lusebrink[1], Maya Evenden[2], Nadir Erbilgin[3]

[1]University of Alberta, Canada, [2]University of Alberta, Canada, [3]University of Alberta, Canada

The Mountain Pine Beetle (Dendroctonus ponderosae) has killed millions of lodgepole pine (Pinus contorta; historical host) trees in British Columbia, Canada and has moved eastwardly into the hybrid zone of lodgepole x jack pine (Pinus banksiana) and more recently into jack pine in Alberta. Our objectives were (1) to develop a chemical profile of volatile organic compounds (VOCs) released from the host trees (P. contorta, P. banksiana); (2) to evaluate if VOC profiles vary with different environmental (ambient vs. water deficit) and biological treatments (fungal inoculation with G. clavigera vs. control). Fungal-inoculated trees release more overall monoterpenes than control trees. Lodgepole pine emitted higher amounts of monoterpenes than jack pine. The effect of water regime on overall volatile emission seems to be species or site specific. Lodgepole and jack pine trees that experienced ambient water conditions emitted more and less total VOCs, respectively, than trees subjected to water deficit for each species. Chemical analysis of the phloem is in process to evaluate the impact of environmental and biological treatments on the chemically-mediated interactions between MPB and its host trees.

Comparisons of the parasitism by four indigenous *Trichogramma* species on the rice striped stem borer, *Chilo suppressalis* at different temperature and relative humidity regimes

Xiaohua Yuan[1], Changchun Ruan[2], Liansheng Zang[3]

[1]Institute of Biological Control, China, [2]Institute of Biological Control, China, [3]Institute of Biological Control, China

The striped stem borer, Chilo suppressalis (Walker), is one of the most economically important rice pests worldwide. However, biological control of this pest using natural-enemy insects has been rarely documented to date. Indigenous natural populations of four Trichogramma species (i.e., T. japonicum, T. chilonis, T. dendrolimi and T. ostriniae) were collected from the eggs of C. suppressalis in paddy field. With the objective of screening suitable candidate species for controlling the striped stem borers, the parasitism of these four Trichogramma species on their native host eggs, C. suppressalis, was evaluated at five temperatures (18, 22, 26, 30 and 34℃) and four relative humidity regimes (30, 50, 70 and 90%). The results indicated temperature and humidity significantly affected the parasitism of all species. Trichogramma chilonis had higher parasistim at 26 ℃ than at other temperature regimes. In contrast, T. dendrolimi, T. ostriniae as well as T. japonicum performed better within a wider-adapted temperature range. All four Trichogramma species parasitized the largest number of C. suppressalis eggs at 70% RH. Parasitism differed significantly among Trichogramma species at all temperatures tested with an exception of 30 ℃and all relative humidity regimes with an exception of 50% RH. Generally, T. dendrolimi and T. japonicum apparently performed better than the other species at 18-26 and 30-34℃, respectively. Whereas, T. ostriniae parasitized the least number of host eggs at 30-70% RH. Both T. dendrolimi and T. japonicum appear to be promising candidates for augmentative release against C. suppressalis in northeastern China.

Nutritional variations affect the larval behaviour of the spruce budworm (*Choristoneura fumiferana* (Clem.).

Roberto Quezada Garcia[1], Darragh Ennis[2], Emma Despland[3], Eric Bauce[4]

[1]Universite Laval, Canada, [2]Concordia University, Canada, [3]Concordia University, Canada, [4]Universite Laval, Canada

The pressure of insect outbreaks can alter the allocation of nutrients in host plants. This re-allocation can directly affect the insect's performance. Low nutritional quality can promote migration to look for a better food resource. To determine whether a nutritional stress effects biological performance and as a consequence feeding behavior, we observed the feeding behavior of 50 larvae of 6th instar spruce budworm (Choristoneura fumiferana Clem.) (Lepidoptera: Tortricidae) during four hours feeding periods. Larvae were reared on two types of artificial diet, a nutritionally-balanced diet and a less suitable diet. The results show that nutritional stress affects behavior and the biological performance of females. Individuals have short periods of feeding and probing, with these behaviors being longer in the second generation. This study suggests that the low quality of foliage induced by long periods of defoliation may cause an active behaviour change in insects feeding on this foliage.

Allopatric distribution and diversification without changing diet in a bryophyte-feeding basal moth lineage (Lepidoptera: Micropterigidae)

Yume Imada[1], Atsushi Kawakita[2], Makoto Kato[3]

[1]Kyoto University, Japan, [2]Kyoto University, Japan, [3]Kyoto University, Japan

The Lepidoptera represents one of the most successful radiations of plant-feeding insects, which predominantly took place within angiosperms beginning in the Cretaceous period. Angiosperm colonization is thought to underlie the evolutionary success of the Lepidoptera because angiosperms provide an enormous range of niches for ecological speciation to take place. By contrast, the basal lepidopteran lineage, Micropterigidae, remained unassociated with angiosperms since the Jurassic but nevertheless achieved a modest diversity in the Japanese Archipelago. We explored the causes and processes of diversi?cation of the Japanese micropterigid moths by performing molecular phylogenetic analysis and extensive ecological surveying. Phylogenetic analysis recovered a monophyletic group of approximately 25 East Asian endemic species that feed on the liverwort Conocephalum conicum, suggesting that niche shifts hardly played a role in their diversi?cation. Consistent with the weak ?ying ability of micropterigid moths, the distributions of the Conocephalum feeders are each localized and allopatric, indicating that speciation by geographical isolation has been the major process shaping the diversity of Japanese Micropterigidae. To our knowledge, this is the largest example of radiation of herbivorous insects that does not accompany any apparent host-plant differentiation.

Determination of the maternal effect of *Aspidiotus nerii* Bouche (Hemiptera: Diaspididae) by using life table

ismail Karaca[1], Senay Ozger[2], Alime Bayındır[3], Mehmet Sedat Sevinc[4]

[1]*Suleyman Demirel University, Turkey,* [2]*Suleyman Demirel University, Turkey,* [3]*Suleyman Demirel University, Turkey,* [4]*Suleyman Demirel University, Turkey*

Aspidiotus nerii Bouche (Hemiptera: Diaspididae) is an excellent host for rearing biological control agents for the control of scale insects. This study investigated the maternal effect on the reproduction and development of A. nerii Crawlers at the 1st, 15th and 30th days were transferred to separate clean potato tubers. After the crawlers settled, each potato was divided into cells of 4 cm2 surface area surrounded by 'Stickem Special' to prevent their escape. When all nymphs in the cell became adults, one female and all the males were left in the cells, and the rest of the females were removed. Experiments were done at 25±0.5 °C, 16:8 hours and 65±1% humidity in a climate chamber. Cells were observed daily; nymphs were removed after counting. Variance analysis and Duncan's multiple range test were applied for statistical analysis. The average number of nymphs produced by 1, 15 and 30 day old nymphs were 208.57, 47.82 and 20.07, respectively. Life table parameters were also calculated. Net reproductive rate (Ro), intrinsic rate of increase (rm) and mean generation time (To) were found to be 104.286, 23.911 and 7.525 females/females/generation, 0.109, 0.078 and 0.057 females/females/day, 42.714, 40.616 and 35.439 days, respectively.

Life Tables Variability: with a mathematical discussion of the application of the jackknife technique to the estimation of the variance of net reproductive rate

Yu-Bing Joyce Huang[1], Hsin Chi[2]

[1]National Chung Hsing University, Taiwan, [2]National Chung Hsing University, Taiwan

Life tables were constructed for Bactrocera cucurbitae on Cucumis sativus L. under simulated field conditions. Eggs were artificially introduced into cucumbers and kept at 25ºC in a growth chamber, and the values of population parameters were measured for two replicates. The intrinsic rates of increase (r) found for the two replicates were 0.1354 and 0.1002 day-1, the net reproductive rates (R0) were 206.3 and 66.0 offspring, and the mean generation times (T) were 39.5 and 42.6 days, respectively. Moreover, for cucumbers kept in the field and covered with leaves, the population parameters (r, R0 and T) for two replicates were 0.0935 and 0.0909 day-1, 17.5 and 11.4 offspring, and 34.0 and 35.0 days, respectively. However, if cucumbers were kept in the field but were not covered, the population parameters (r, R0 and T) for two replicates were 0.1043 and 0.0904 day-1, 27.7 and 10.1 offspring, and 32.8 and 27.2 days, respectively. These results showed that life tables constructed in the laboratory can differ significantly from life tables constructed using field data. Moreover, our results revealed significant variability between replicates. The differences between life tables and the variability between replicates found by this study must be considered in practical applications of life tables in pest management. The mathematical analysis shows that the jackknife technique generates biologically meaningless values of net reproductive rate and consequently results in overestimation of its variance. We suggest that the jackknife technique should not be used for the estimation of variance of the net reproductive rate.

Effect of host plant on feeding, biological and morphological parameters of *Liriomyza huidobrensis* Blanchard (Diptera: Agromyzidae)

Caroline A. Okoth[1], Adenirin Chabi-Olaye[2], Komi K. M. Fiaboe[3], Arop L. Deng[4], Isaiah M. Tabu[5]

[1]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [2]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [3]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [4]Egerton University, Njoro Campus, Kenya, [5]Egerton University, Njoro Campus, Kenya

Liriomyza huidobrensis (Blanchard) is a quarantine key pest to the horticultural sector in East Africa. To understand its behavior for formulation of suitable management strategy, a study was conducted to determine the effect of host plant on its performance. Vicia faba L., Phaseolus vulgaris L., Pisum sativum L. and Lycopersicon esculentum M. were evaluated for their suitability for feeding, oviposition, survival and development of L. huidobrensis under both no-choice and choice conditions, simulating monoculture and intercrop systems, respectively. Lycopersicon esculentum was the preferred host with mean feeding punctures/cm2 of 23.34±3.35 and 11.59±1.36 and mean number of eggs/ cm2 of 0.57±0.11 and 0.08±0.04 for the no-choice and choice conditions, respectively. It was however the least suitable for development of L. huidobrensis, with the lowest number of pupae and adults (2.50±0.73 and 1.38±0.46 respectively), survival rate of 6.05±1.95% and fitness as measured by female and male wing length of 1.84±0.04mm and 1.57±0.03mm, respectively. This makes it a good candidate trap crop for management of this pest. Vicia faba, on the other hand, was the most suitable for development of the pest (42.88±11.80 pupae and 32.13±8.77 adults), survival (65.01±13.86%) and fitness (2.18±0.03mm and 1.77±0.04mm), making it a suitable host for mass rearing of L. huidobrensis. Previous experience (rearing history) of the pest significantly affected the selection for feeding and egg laying, but did not affect host suitability for development. Liriomyza huidobrensis fed and oviposited significantly more under no-choice condition than choice set-up suggesting the potential of mixed cropping in controlling L. huidobrensis infestations.

Population dynamics and 'outbreaks' of Diamondback moth, *Plutella xylostella*, inGuangdong province, China: Climate or the failure of management?

Zhenyu Li[1], Myron Philip Zalucki[2], Xia Feng[3]

[1]Guangdong Academy of Agricultural Sciences, China, [2]University of Queensland, Australia, [3]Guangdong Academy of Agricultural Sciences, China

Diamondback moth, or DBM, became the major pest of brassica vegetable production in Guangdong, a province in south-eastern China, in the late 1980's and has continued to challenge growers, particularly during the spring and autumn. Control has relied on insecticides and, as has happened in other parts of the world, resistance to these has evolved and subsequent field control failures have occurred. We review and summarize the history of DBM management in Guangdong. We show that the geographic distribution of the pest in China is well described by a simple climate niche model. Our model predicts the seasonal phenology and some of the variation in abundance amongst years in Guangdong. Discrepancies may reflect migration and insecticide use at a landscape level. The scale of the pest problem experienced varies with management practices. Local production breaks, and strict post harvest hygiene are associated with lower pest pressure on large scale production units. As more and more insecticides become ineffective the need to implement an IRM (Insecticide Resistance Management) strategy, as well as basic IPM (Integrated Pest Management) practices, will become more pressing. The potential use and development of a better forecasting system for DBM that will assist these 30 developments is outlined.

Effects of cold storage on survival, predation and reproduction of pre-wintering *Harmonia axyridis* (Pall)

Changchun Ruan[1], Wenmei Du[2], Liansheng Zang[3]

[1]Institute of Biological Control, Jilin Agricultural University, China, [2]Institute of Biological Control, Jilin Agricultural University, China, [3]Institute of Biological Control, Jilin Agricultural University, China

The multicolored Asian ladybird beetle, Harmonia axyridis (Pallas), is considered an important generalist predator against aphids, mealybugs, scale insects and spider mites. There are currently abundant natural resources of overwintering H. axyridis in Asia and North America. The availability of an adequate cold storage method would enable the use of field-collected pre-wintering ladybirds for pest suppression in the following season. We studied the effect of cold storage (30, 60, 90, 120 and 150 days stored at -3, 0, 3 and 6 ℃) on survival, fecundity and predation in field-collected populations. The survival of both female and male ladybirds decreased significantly as storage duration increased at -3 and 0 ℃. The ladybirds showed more than 80% survival when they were stored for 150 days at 3 and 6 ℃. Long-term cold storage had different effects on the fecundity of H. axyridis at different temperatures. Prolonged cold storage at both 3 and 6 ℃ shortened their pre-oviposition duration and had no adverse effect on reproductive capacity as compared to that of unstored individuals. The adults that experienced 90-day storage at 0 ℃ had the shortest pre-oviposition duration and the largest reproductive capacity. The individuals that were stored for 150 days at 3 ℃ consumed significantly more aphids than the unstored ones. Generally, 3-6 ℃ is a suitable temperature for cold storage of the ladybird without any reduction in fitness. This study will help the exploitation and application of pre-wintering H. axyridis for the biological control of insect pests.

Transmission rate of rice stripe virus by *Laodelphax striatellus* from different geographical population

Fang Liu[1], Qing Qing Gui[2]

[1]*Yangzhou University, China,* [2]*Yangzhou University, China*

The small brown planthopper, Laodelphax striatellus (Fallen) can transfer the Rice stripe virus (RSV) to host plants, which then develop rice stripe disease. RSV is a typical member of the genus Tenuivirus, and is transmitted in the circulative/persistent manner by L. striatellus. There are two paths for virus transmission between vectors. One is transovarially transmitted to progeny from infected parents (vertical transmission), and the other is horizontal transmission by sucking infected plants. We examined horizontal, vertical and mixed (including horizontal and vertical) transmission rates of RSV by L. striatellus from one not-epidemic area (Fuyang in Zhejiang province) and three epidemic areas (Yangzhou and Peixian in Jiangsu Province, and Donggang in Liaoning province). The results indicated that RSV acquisition rate of naive L. striatellus from four populations were not significantly different. RSV transmission rate to healthy rice plants by viruliferous L. striatellus in Fuyang population was significantly lower than those in Yangzhou, Donggang and Yangzhou populations. Vertical transmission abilities and mixed transmission abilities of infective L. striatellus in the first generation in tested populations were similar. But in the fourth generation, ratio of RSV-positive offspring individuals from an infective mother in Fuyang population was significantly lower than those in Xuzhou, Yangzhou and Donggang populations. Different transmission abilities of L. striatellus in different populations can have two explanations: either the population genetic structure of RSV was different, or L. striatellus from 4 populations were heterogeneous.

Keywords:*Laodelphax striatellus, Rice stripe virus (RSV), RSV transmission ability, geographical population*

Effect of temperature on the developmental period, survival and adult longevity of *Sesamia nonagrioides* (Lepidoptera: Noctuidae)

Stefanos S. Andreadis[1], Nikolaos K. Kagkelaris[2], Panagiotis A. Iliopoulos[3], Matilda Savopoulou-Soultani[4]

[1]Aristotle University of Thessaloniki, Greece, [2]Aristotle University of Thessaloniki, Greece, [3]Technological Educational Institute of Larissa, Greece, [4]Aristotle University of Thessaloniki, Greece

The effect of temperature on development, longevity and survival of the corn stalk borer Sesamia nonagrioides Lefebvre (Lepidoptera: Noctuidae), has been investigated in the laboratory. The duration of development of egg, 1st, 2nd, 3rd, 4th, 5th larval instar and pupa, as well as adult longevity, at five constant temperatures (14, 17, 21, 25 and 31℃) was measured. Development time decreased significantly with increasing temperature within the range 14-25℃. Survival was higher at medium temperatures (17 to 25℃) in comparison with that at more extreme temperature regimes (14 and 31℃). Duration of all developmental stages differed significantly among various temperatures. Experimental individuals demonstrated low total survival rate (9.3-34.1%) at all temperature regimes. Egg and 1st instar larvae were the stages where S. nonagrioides suffered the highest mortality levels at all temperatures. Thermal requirements of development (developmental thresholds, thermal constant, optimum temperature) were estimated with application of a linear and one non-linear model (Logan I). Upper and lower developmental thresholds ranged between 31.2-36.2℃ and 7.0-10.3℃, respectively. Optimum temperature for development was estimated at between 28.1-30.3℃. The thermal constant for total development was estimated 1000.0 day-degrees. Adult longevity of S. nonagrioides ranged between 6.0 ?17.3 days and decreased with increase in temperature only within the range 14-25℃. Differences between two successive temperatures were significant only between 14 and 21℃. The Weibull distribution was used to describe the age specific survival, which in S. nonagrioides is of "Type I", as the risk of death increases with age.

Cold adaptation coupled with population expansion during the ice age in the pollinating wasp *Wiebesia pumilae* (Hymenoptera: Agaonidae) of Ficus pumila

Hurng-Yi Wang[1], Chia-Hung Hsieh[2], Chin-Gi Huang[3], Sui-Wah Kong[4], Hsiao-Chi Chang[5], Ho-Huei Lee[6], Shih-Lun Chen[7], Hsy-Yu Tzeng[8], Wen-Jer Wu[9]

[1]National Taiwan University, Taiwan, [2]National Taiwan University, Taiwan, [3]National Taiwan University, Taiwan, [4]National Taiwan University, Taiwan, [5]National Taiwan University, Taiwan, [6]National Taiwan University, Taiwan, [7]National Taiwan University, Taiwan, [8]National Chung Hsing University, Taiwan, [9]National Taiwan University, Taiwan

In order to study genetic interactions between host figs and their pollinating wasps and the influence of climatic changes on their genetic structures, we sequenced both cytoplasmic and nuclear genes and genotyped nuclear microsatellite loci from two types of Ficus pumila, the widespread creeping fig and the endemic jelly fig, and from their pollinating wasps, Wiebesia pumilae, found in Taiwan and on nearby offshore islands. Between the two pollinating wasps, the level of divergence in the mitochondrial cytochrome c oxidase subunit I (mtCOI) gene was more than 50-times higher than the two nuclear segments sequenced. In addition, we found an excess of amino-acid substitutions in mtCOI, especially in the lineage leading to jelly-fig wasps. Both nuclear intron and microsatellite loci of jelly-fig wasps showed signs of population expansion beginning during the last glacial age. Finally, jelly-fig wasps lived longer in low (20 °C) than in high (25 and 30 °C) environmental temperatures in survival tests. All of the above results indicate its adaptation to a cold environment, which probably has been facilitated by glacial epochs as the estimation of the time to the most recent common ancestor suggested. Between the two fig plants, a complete segregation of chloroplast DNA was observed, but there was no sign of isolation in nuclear markers, suggesting that the two types of fig trees are still genetically linked. Finally, according to the molecular clock, histories of their local colonization, population demographics, and the formation of current distributions were nicely coupled with past climatic changes.

Transplanting large potted trees: a factor involved in the range expansion of the pine processionary moth, *Thaumetopoea pityocampa*.

Christelle Robinet[1], Charles-Edouard Imbert[2], Jerome Rousselet[3], Daniel Sauvard[4], Jacques Garcia[5], Francis Goussard[6], Alain Roques[7]

[1]INRA, France, [2]INRA, France, [3]INRA, France, [4]INRA, France, [5]INRA, France, [6]INRA, France, [7]INRA, France

Pine processionary moth, Thaumetopoea pityocampa, is expanding its range northwards and upwards in response to climate warming. The natural spread in latitude was estimated at ca 5.6 km per year during the last 10 years in the southern Paris Basin. However, additional pioneer colonies were recently detected far from the northern edge of the range, and notably near downtown Paris. A study combining several approaches was conducted to determine the origin of these pioneer colonies First, the shortest distance between the pioneer colonies and the previously-infested locations was calculated, and this distance was compared to the female flight distance measured on a flight mill. We found that most of pioneer colonies could not result from natural dispersal. Then, some individuals from the pioneer colonies were genotyped and compared to populations of different areas in France and neighbouring countries. We found that several pioneer colonies had higher probabilities to originate from the southern Mediterranean area than from the northern edge, suggesting a dispersal at very long distance and accidental human transportation. Finally, the presence of natural enemies associated with different life stages of the pine processionary moth was assessed. We found a parasitoid species specific of pine processionary pupae indicating that this natural enemy was probably transported along with moth pupae. These convergent results suggest that pioneer colonies may result from the transportation of large potted trees including pupae in the accompanying soil. Consequently, both global warming and human-mediated dispersal are involved in the range expansion of this insect.

Predator's non-consumptive effects on herbivores influence herbivore-induced plant responses

Shigeaki Hirano[1], Shunsuke Utsumi[2], Takayuki Ohgushi[3]
[1]Kyoto University, Japan, [2]University of Tokyo, Japan, [3]Kyoto University, Japan

Species change their traits morphologically, physiologically, behaviorally in response to the presence of other species, and these trait changes influence indirectly other interacting species, which is called trait-mediated indirect interaction (TMII). Previous studies have revealed that TMIIs play important role in organization of ecological communities. However, the little is known whether trait change of one species affect the trait changes of other species. To understand the dynamics of TMIIs, we must consider how trait changes interacting with each other. There is increasing appreciation that non-consumptive effects of predators often reduces feeding activity and/or trigger habitat shift of herbivores, which, in turn, increases plant biomass. On the other hand, plants also change their traits in response to the herbivore attack. The magnitude of induced plant responses is largely dependent on patterns of herbivory, such as the amount of damage and position receiving damage. Hence, we hypothesize that predators can alter herbivore-induced plant responses through a behavioral shift of herbivores. We conducted a field experiment to test the hypothesis, using a tri-trophic system of a willow, leaf beetle larvae, and a flower spider. The experiment had four treatments: lethal (tri-trophic with a spider) and risk (tri-trophic with a manipulated predator whose chelicerae were glued), no predator (bi-trophic), and control (plant alone) treatments. We found that spiders' non-consumptive effects suppressed the induced chemical change of willow leaves.

Inferring the difference of moth fauna composition in subtropical alpine forests - A case study in Hohuanshan Mountain Range, Taiwan

Wei-Chun Chang[1], Hsu-hong Lin[2], Li-chen Shih[3], Shipher Wu[4]

[1]Council of Agriculture, Executive Yuan, Taiwan, [2]Council of Agriculture, Executive Yuan, Taiwan, [3]Council of Agriculture, Executive Yuan, Taiwan, [4]National Taiwan University, Taiwan

The moth fauna in Taiwan is continuously explored in these 20 years after the checklist of "Lepidoptera of Taiwan" published in 1992. The efforts of moth study, especially the alpha-taxonomy and hostplant recording, facilitate the subsequent ecological and environmental monitoring using moths as target taxa. Here we present the fundamental moth survey in medial section of the Central Mountain Range in Taiwan, Hohuanshan area, to understand (1) the influences of altitude and vegetational changes between cold and warm needle-leaf forests towards moth fauna and (2) detailed occurrence time, family composition of high altitude moths in Taiwan. Two sites, Hsiaofengko (3002m) and Chin-ma tunnel (2405m) are selected for conducting fundamental moth surveys between April, 2006 to November 2009 and Feburary 2008 to December 2009, respectively. Totally 15 families, 245 species and 4179 individuals are collected and identified. The difference in species numbers (141 and 170 species respectively) and low coefficient of similarity under Sorensen index (38.6%) reveal different moth composition, hitherto hostplant records of sampled species or cogeneric taxa in neighboring countries are adopted to infer the restriction effects of moth distribution. Moth sampling conducted more than one year uncovers different high peak of occurrence time. Moth numbers of higher site increase gradually from February and then decrease from September, however, that of lower site shows an additional peak from March to May, causing mainly in the occurrence of univoltine, spring flyer Geometridae and Noctuidae. Our works provide first comparison of moth fauna composition of subtropical high-altitude region in Taiwan.

Effect of genital spines on male fitness in the West Indian sweet potato weevil

Norikuni Kumano[1], Takashi Kuriwada[2], Keiko Shiromoto[3], Haruki Tatsuta[4]

[1]Okinawa Plant Protection Center, Japan, [2]Okinawa Plant Protection Center, Japan, [3]Okinawa Plant Protection Center, Japan, [4]Ryukyu Univ., Japan

In many animal species, including insects, the morphology of the male genitalia is diverse. One of the most enigmatic observations in evolutionary biology is the evolution of morphological traits of male to physically injure female. It is unclear why males inflict the wound, but it has been suggested that males evolve harmful traits to induce favorable responses for males, such as delayed remating or increased rates of oviposition. The male West Indian sweetpotato weevil, Euscepes postfasciatus (Fairmaire) (Coleoptera: Curculionidae), possesses spines on the endophalus of the intromittent organ, and this spiny area is able to divide into two types. One is a band-shaped area with many short spines, and the other is an island-shaped area with several long spines. Both the standardized shape of the spines or the number of spine are significantly different between the two areas. These traits of male genital spines would affect the male reproductive success through the response of the partner. To explain the role of harmful male genital traits, we investigate the relation between the morphological character of male genitalia and fitness in E. postfasciatus. Furthermore, we investigate the narrow-sense of heritability and the phenotypic and genetic correlations for some traits. We will discuss the adaptive significance of the harmful genitalia in this weevil.

Boldness, mate choice and bacterial resistance in the field cricket *Gryllus integer*

Raine Kortet[1], Petri Toivo Niemela[2], Anssi Vainikka[3], Jouni Laakso[4]

[1]University of Eastern Finland, Finland, [2]University of Eastern Finland, Finland, [3]University of Eastern Finland, Finland, [4]University of Helsinki, Finland

Recent theory predicts that personality traits contributing to resource intake rates could reflect individual's condition-dependent capacity to resist pathogens. Since females often prefer mates with strong immune defence, females could potentially gain fitness benefits by using male's behavioural type (BT) as one mate choice criteria. We studied if females in the field cricket Gryllus integer would base their mate choice on male general boldness and if the boldness would predict survival under experimental challenge to opportunist bacterial pathogen Serratia marcescens. In addition, we tested if different females would prefer the same males. In general, females showed tendency to prefer bold males. Our results suggest that females may show preferences for certain BTs, but that male boldness may not reflect his capacity to resist bacterial pathogens.

Variation in supercooling capacity of *Tribolium confusum* (Coleoptera: Noctuidae), *Oryzaephilus surinamensis* (Coleoptera: Silvanidae) and *Trogoderma granarium* (Coleoptera: Dermestidae)

Stefanos S. Andreadis[1], Christos G. Spanoudis[2], Panagiotis A. Iliopoulos[3], Matilda Savopoulou-Soultani[4]

[1]Aristotle University of Thessaloniki, Greece, [2]Aristotle University of Thessaloniki, Greece, [3]Technological Educational Institute of Larissa, Greece, [4]Aristotle University of Thessaloniki, Greece

Physical control methods, such as low temperatures, have been extensively used to control stored product insects. Herewith, we examined the cold tolerance of the confused flour beetle, Tribolium confusum Jacquelin du Val (Coleoptera: Tenebrionidae), the sawtoothed grain beetle, Oryzaephilus surinamensis (L.) (Coleoptera: Silvanidae) and the Khapra beetle, Trogoderma granarium Everts (Coleoptera: Dermestidae), using measures of supercooling point relative to developmental stage. Generally, all species presented an enhanced capacity of supercooling, as supercooling points ranged from -16.8 to -22.6℃. Developmental stage appeared to affect the superooling ability of all species significantly. More specifically, adults of O. surinamensis and T. granarium displayed a significantly higher ability to supercool in relation to its respective larvae. Only in the case of T. confusum, adults showed a decreased supercooling capacity (-16.8℃) in relation to larvae (-19.1℃). Moreover, adults of T. confusum were less capable to supercool in relation to those of O. surinamensis and T. granarium, while no significant differences were observed between larvae of the different species. Furthermore, we measured the latent heat which was released right after individuals were supercooled. In all species larvae released a higher amount of latent heat compared to adults. The highest amount of latent heat was observed for larvae of T. granarium (4.7℃) whereas the lowest for adults of T. confusum and O. surinamensis (1.7℃). Overall, no significant correlation between supercooling point and latent heat was observed among all the treatments. Our results are discussed in terms of using low temperatures to control these particular stored product insects.

Characterization of an atypical tree-aphid interaction model: *Phloeomyzus passerinii* (Signoret) (Hemiptera: Aphididae) on the stem of different poplar genotypes

Sophie Pointeau[1], Arnaud Ameline[2], Aurelien Salle[3], Francoise Laurans[4], Stephanie Bankhead-Dronnet[5], Francois Lieutier[6]

[1]University of Orleans, France, [2]University of Amiens, France, [3]University of Orleans, France, [4]INRA Orleans, France, [5]University of Orleans, France, [6]University of Orleans, France

The woolly poplar aphid, Phloeomyzus passerinii (Sign.), lives on poplar trunks and causes cortical necroses leading to the death of trees where infestation is heavy. While this aphid is a major pest in poplar plantations in Southern Europe and the Near East, interactions between P. passerinii and poplar are poorly known. We have investigated (1) the feeding behavior of P. passerinii and (2) the impact of poplar resistance factors on colonization process. Studies were conducted on three Populus x canadensis Moench genotypes: 'I214' (susceptible), 'Brenta' and 'I45/51' (both resistant). Using histology and electrical penetration graphs (EPG) with aphids feeding on 'I214', we showed that P. passerinii fed upon the cortical parenchyma cells with an exceptional plant penetration strategy. The atypical EPG signal of P. passerinii was separated into two main phases: an intra-and intercellular pathway phase and a sustained intracellular phase in cortical parenchyma cells. The type and location of poplar resistance factors were defined by combining analyses of P. passerinii's performance and probing behavior (EPG) on the three P. x canadensis genotypes. P. passerinii encountered no resistance factors before its stylet reached the cortical parenchyma layer. Both resistant genotypes showed parenchyma-located antibiotic properties but characteristics were distinct according to the genotype. The genotype 'Brenta' showed additional parenchyma-located antixenosis.

Effect of temperature on development and growth of *Propylea japonica* and *Harmonia axyridis* reared on *Megoura japonica*

Shize Zhang[1], Hongwei Shan[2], Tongxian Liu[3], Fan Zhang[4]

[1]Northwest A & F University, China, [2]Northwest A & F University, China, [3]Northwest A & F University, China, [4]Beijing Academy of Agricultural and Forestry Sciences, China

Megoura japonica feeds on a variety of fabaceous plants in the genus Vicia and Lathyrus. Propylea japonica and Harmonia axyridis are indigenous to China, and also very important aphidophagous coccinellids. Since M. japonica was so easy for laboratory mass-rearing in broad bean plants as well as high reproduction, it may be useful for laboratory mass-rearing of P. japonica and H. axyridis. Preimaginal development, survival, sex ratio, size and weight upon reaching the adult stage of P. japonica and H. axyridis, which fed on M. japonica on broad bean plants, were examined at three constant temperatures (20, 25 and 30℃) and 16L: 8D. Total preimaginal development ranged from 22.5 to 24.2 days at 20℃, and to 9.3 and 14.1 days at 30 ℃ in P. japonica and H. axyridis, respectively. The larval and pupal survival decreased with the increasing of temperature. Larval and pupal survival was highest at 20 ℃ reaching 89.7 and 89.7%, and 90.0 and 86.7%, lowest at 30 ℃ reaching 60.7 and 45.0%, and 72.7 and 54.6% in P. japonica and H. axyridis, respectively. Heavier and larger adults of P. japonica and H. axyridis were obtained at 20℃, while temperature did not significantly affect the adult weight and size during 25 to 30 ℃, though the ladybirds were heavier and larger at 30 ℃. The sex ratio of P. japonica and H. axyridis was 0.44, 0.55 and 0.40, 0.53, 0.50 and 0.33 at 20, 25 and 30℃, respectively.

Foraging decisions of insect parasitoids under the threats of intraguild predation

Yoshitaka Nakashima
Obihiro University of Agriculture & Veterinary Medicine, Japan

Aphids are attacked by a large guild of natural enemies. Intraguild (IG) interactions are widespread in aphid natural enemy communities. Immature stages of aphid parasitoids often become IG prey in interactions between predators and parasitoids operating in the same guild, and so adult parasitoids would benefit by developing avoidance responses to cues from IG predator species living in the same habitats in order to reduce predation risks to their offspring. Diverse tactics of IG predator avoidance by aphid parasitoids are shown in different two systems related to pea aphid and cowpea aphid. These tactics are 1) IG predator avoidance using chemical cue left by the ladybird Coccinella septempunctata by aphid parasitoids, Aphidius and Praon species, 2) avoiding IG predation by allocating much more searching time of aphid parasitoid, Lysiphlebus fabarum, in patches with foot stamp of ants that protect aphid colonies against IG predators, and 3) host manipulation by immature parasitoids making parasitized aphids move to ground surface from plants just before aphid mummification.

Mite predator-prey relationships in citrus could be disentangled by use of Multiplex PCR

Consuelo Perez-Sayas[1], Tatiana Pina[2], Marian Gomez-Martinez[3], Josep Anton Jacas[4], Monica A. Hurtado[5]

[1]Universitat Jaume I (UJI), Spain, [2]Universitat Jaume I, Spain, [3]Universitat Jaume I (UJI), Spain, [4]Universitat Jaume I (UJI), Spain, [5]Universitat Jaume I, Spain

Multiplex PCR has been proved to be a useful molecular tool to detect and identify the citrus-feeding tetranychid mites Tetranychus urticae and Panonychus citri, and their main natural enemies, which in the Region of Valencia (Eastern Spain) are Euseius stipulatus, Phytoseiulus persimilis, Neoseiulus californicus, Neoseiulus barkeri, and Typhlodromus phialatus. Squash-capture and tissue-print of field-collected phytoseiid mites followed by Multiplex PCR has revealed to be a valid alternative to classic taxonomy for mite identification and has allowed a better knowledge of mite trophic interactions occurring in citrus orchards. Furthermore it has allowed to establish prey preferences under real field conditions. Under these conditions, the generalist pollen-feeder E. stipulatus behaves as an omnivorous species that does not seem to prey preferentially on T. urticae even when this species is highly abundant, whereas the specialist P. persimilis clearly prefers T. urticae even when this prey is scarce.

Visual and chemical cues attracting rednecked cane borer, *Agrilus ruficollis*, to primocanes

Soo-Hoon Samuel Kim[1], Clinton E. Trammel[2], Barbara Lewis[3], Donn T. Johnson[4]

[1]University of Arkansas, U.S.A., [2]University of Arkansas, U.S.A., [3]University of Arkansas, U.S.A., [4]University of Arkansas, U.S.A.

Blackberry production in the eastern US faces an insect pest that threatens nearly all the 7,100 tons of fruit produced annually from 2,500 acres of blackberries in the eastern North America. The rednecked cane borer has been shown to affect nearly 72% of blackberry canes and predisposes galled canes to winter injury. This pest only oviposits onto blackberry primocanes. Experiments were conducted to determine the visual and chemical cues attracting the pest to primocanes. Visual cues consisted of testing cane and leaf color mimicked traps. Traps consisting of primocane (leaf and cane), floricane (leaf and cane), yellow, purple, and control colors were placed in two locations to test for attractiveness of the trap. Chemical cues were tested by collecting plant volatiles from primocanes and floricanes, analyzing the collected volatiles on GC/MS and testing response by GC/EAD. Results from the trapping experiment showed a significantly higher number of borers trapped on the primocane and floricane colored cylindrical cane-mimic traps when compared to the control ($P < 0.05$), but not for rectangular leaf-mimic traps. Results from the chemical cue will show there is a volatile profile from primocanes that elicits an antenna response that is not observed from floricanes. Further research into developing the visual and chemical cues for this pest is necessary to develop effective monitoring programs and/or trapping systems to reduce pesticide applications.

Oviposition strategy of the winter cherry bug in response to egg parasitism risk

Yuji Nakajima[1], Tsuyoshi Wakamura[2], Kenji Fujisaki[3]

[1]Kyoto University, Japan, [2]Kyoto University, Japan, [3]Kyoto University, Japan

In organisms providing no parental care, survival and development of offspring strongly depend on both timing of oviposition and choice of oviposition site by mothers. Under natural conditions, the most appropriate oviposition timing and site can change in a situation-dependent manner because biotic and abiotic factors affecting survival and development of offspring often fluctuate spatiotemporally. The winter cherry bug, Acanthocoris sordidus (Thunberg) (Heteroptera: Coreidae), has a unique oviposition strategy. Females of A. sordidus deposit their eggs not only on host plants but also off host plants. On Amami Island, Japan (28°24'N, 129°35'E), most egg clusters of A. sordidus are observed on fallen leaves around the base of host plants. Our previous study showed that the parasitism rate of eggs by Gryon philippinense (Ashmead) (Hymenoptera: Scelionidae), which is a predominant parasitoid, is lower on fallen leaves than on host plants. On the other hand, oviposition off host plants increases nymphal mortality by imposing host searching costs on nymphs. We investigated whether A. sordidus females of Amami Island population change oviposition behavior in response to egg parasitism risk by G. philippinense. Our study revealed that A. sordidus's oviposition rate was lower in the presence of parasitoids than in the absence. In addition, females which had been enclosed with parasitoids 24h just before a trial showed stronger preference for fallen leaves as oviposition substrate than females which had not. We concluded that A. sordidus females can increase their fitness by spatial-temporal avoidance of G. philippinense.

Differential responses to predator cues between two mosquito species breeding in different habitats

Shin-ya Ohba
Nagasaki University, Japan

Natural selection favours females who can correctly assess the predation risk and hence avoid high-risk oviposition sites and reduce the mortality rate of their offspring. Despite the potential significance of such behaviour, relatively few studies have assessed the relationship between oviposition behaviour and predation risk. The present study aimed to determine the sublethal effects of predators on oviposition site selection by gravid females, the foraging activity of larvae, and the life history traits of 2 mosquito species that breed in different habitats, Aedes albopictus (container breeder) and Culex tritaeniorhynchus (wetland breeder). Female C. tritaeniorhynchus avoided laying eggs at oviposition sites in the presence of a predator cue. In contrast, female A. albopictus laid eggs in both the absence and presence of the predator cue. To examine the effects of predator cues on larval behaviour, experiments were conducted in the absence and presence of a predator cue. Although larval activity was lower in the presence of the predator cue than that in its absence in both species, C. tritaeniorhynchus responded to the predator cue more strongly than A. albopictus. Female A. albopictus that had been reared with caged predators exhibited an extended larval development period, whereas the adult C. tritaeniorhynchus reared in the presence of predators were smaller than those reared in their absence. This finding might explain why C. tritaeniorhynchus avoid laying eggs in predator-conditioned water; i.e., to increase the fitness of their offspring, but A. albopictus either cannot detect predator cues or are not sensitive

The distribution and diversity of butterfly (Lepidoptera) assemblages in King Saba Dalindyebo (KSD) Local Municipality, Eastern Cape, South Africa

Augustine Suh Niba[1], Derick Nomuh Forbanka[2]

[1]Walter Sisulu University, South Africa, [2]Walter Sisulu University, South Africa

Butterflies (Lepidoptera) have attracted more attention as indicators of terrestrial ecosystems than other invertebrates. The study determined butterfly species turnover at a-priori-selected habitat patches in Nduli Nature Reserve and its surrounding (non-protected) landscape within the KSD Local Municipality and their response to measured environmental variables. Using the line transect survey methods, 516 butterfly individuals belonging to 22 species were recorded from 16 sampling units. Species dominance curves showed more butterfly species evenness at sites outside the reserve area than inside. Also, habitat patches outside the Nduli Nature Reserve were richer in butterfly species and overall abundance than inside the reserve. Hierarchical clustering using Bray-Curtis similarity matrices grouped sampling units according to butterfly indicator species sampled. Furthermore, Canonical Correspondence analysis (CCA) results indicated that certain site variables such as percentage herb cover, area of patch size, average grass height, grazing intensity, and average flower density accounted for species distribution patterns across sites. The conservation implications of the study suggests that patch level management of habitats with sufficient flowering herbs and other structural vegetation within and outside the reserve area can encourage both rare and common butterfly species.

Collective decision making during house hunting in the small-colony ant *Myrmecina nipponica*

Adam L. Cronin
Iwate University, Japan

Social insects organise group actions, such as colony relocation, through collective decision making processes. The choice of a place to live is a critical collective decision with profound fitness implications for all colony members. This process has been intensively studied in honeybees and Temnothorax ants, but data on other species are lacking. In this study, I examined the process of collective decision making during colony relocation in the ant Myrmecina nipponica, a small colony ant. Relocation was characterised by a multi-step process; approximately half the colony acts as scouts, searching the available area independently. Gradually a pheromone trail is established to a preferred site, which leads to an accumulation of ants at the new site. This in turn produces a quorum response that is highly dependent on colony size, and a switch to brood transport occurs. The final phase of brood transport and movement of remaining individuals is relatively rapid. There was no tandem-running or carrying behaviour observed, and all individuals made their own way to the new site. Compared to other taxa examined, relocation in M. nipponica is characterised by a high level of individual assessment and apparently limited information exchange, though pheromone trails are clearly important in facilitating navigation to the new site and may be one of several positive feedback mechanisms.

Host plant preference for nesting by the Japanese foliage spider, *Cheiracanthium japonicum* (Araneae: Miturgidae)

Yutaka Hironaka[1], Hiroshi Abe[2]
[1]*Yokahama National University, Japan,* [2]*Nihon University, Japan*

A Japanese foliage spider, Cheiracanthium japonicum, builds nests with plant leaves. The nests are classified into seven types in relation to the seasons and purposes of nesting. We investigated whether the spider selects a plant species according to the nest type and how the physical traits of leaves influence the spider's plant selection. The difference between the composition of the host plant species used for nesting and that of the seasonal vegetation cover was confirmed. This suggests that the spider chooses the host plant species regardless of its abundance in their habitat. Early juveniles use small living or large dead leaves of various plant species to build molting nests. Females prefer long and large leaves found in Miscanthus sinensis and Phragmites japonica over other plant leaves to build breeding nests.

Effects of plants growth promoting rhizobacteria (PGPR) and fertilization on three *Brassicaceae* species and growth performance of *Spodoptera litura*

Yuwatida Sripontan[1], Shaw-Yhi Hwang[2]

[1]National Chung Hsing University, Taiwan, [2]National Chung Hsing University, Taiwan

The objective of this study was to assess the effect of plant growth promoting rhizobacteria (PGPR) and fertilizer on three Brassicaceae species [cabbage (Brassica oleracea L. var. capitata L.), Chinese cabbage (Brassica pekinensis L.) and radish (Raphanus sativus L.)] and growth performance of cutworm Spodoptera litura. Three plants were growth from seeding in the greenhouse. To evaluate the effects of PGPR (application method) and fertilization on plant's performance, four treatments were included in this study: (1) PGPR (drench and seed coating) with fertilizer, (2) only PGPR (drench and seed coating), (3) only fertilizer, and (4) control. The results revealed that plant biomass (root and shoot weight) were higher in both PGPR-seed coating and PGPR-seed coating with fertilizer treatments. To evaluate the effect of foliage on growth performance of Spodoptera litura on the three plants, four treatments were conducted: (1) PGPR-seed coating with fertilizer, (2) only PGPR seed coating, (3) fertilizer only, and (4) control. The results showed that those larvae fed on PGPR-seed coating with fertilizer treatment had better performance, higher growth rate and food processing efficiency. We concluded that PGPR in combination with fertilizer can increase plant's biomass and may play an important role in affecting the growth performance of Spodoptera litura.

Consequence of bio-diversity of aquatic organisms in paddy fields: Influence of two aquatic organisms on rice plant growth

Takayuki Tsukamoto[1], Dina Wahyu Trisnawati[2], Satoru Sato[3], Hironori Yasuda[4]
[1]Yamagata University, Japan, [2]Iwate University, Japan, [3]Yamagata University, Japan, [4]Yamagata University, Japan

In recent years organic farming is well-known as the environmental friendly agriculture. Although many researches done in paddy fields have showed the difference in arthropod abundance between conventional and organic fields, there are few studies to reveal whether the abundance in aquatic organisms was influenced by the farming system and the effects of aquatic organisms on terrestrial arthropod abundance through rice plant growth. We have conducted field studies in conventional and organic paddy fields to compare the abundance in the arthropods between the two fields. The abundance of mosquito larvae was higher in conventional fields, while the abundance in aquatic predators was difference in conventional and organic fields. Abundance in mosquito larvae might influence on abundance of polypagous organisms like spiders as numerical response after they emerged adults. Results revealed that abundance in spiders at conventional fields was higher than organic fields where the abundance in larval mosquitoes was low. In addition, many pond snails were observed only in organic fields, although there were a lot of tadpoles in both fields. We carried out 2x2 factorial experiments to reveal how presence of a snail and tadpoles influences on rice plant growth. Growth of rice plants at the treatments with a snail and tadpoles tended to be higher than other treatments. We would discuss the influence of aquatic organisms on abundance of terrestrial arthropods and rice plant growth.

Symbiotic gut protists are not harbored in termite queens and kings with mature reproductive organs

Keisuke Shimada[1], Osamu Kitade[2], Kiyoto Maekawa[3]

[1]Ishikawa Museum of Natural History, Japan, [2]Ibaraki University, Japan, [3]University of Toyama, Japan

In termites, eusociality involving reproductive division of labor and symbioses with cellulolytic gut microbes are two major biological features of great interest to many entomologists. However, these features have been recognized as independent phenomena, probably due to a lack of understanding of the relationship between gut symbionts and reproductive castes. In this study, to determine the relationship between symbiotic protists and reproductives of Reticulitermes speratus, we measured the number of gut protists (including Trichonympha agilis, Pyrsonympha grandis and Dinenympha exilis) and size of guts and reproductive organs of primary and secondary reproductives together with other castes in different stages of colony development. The primary reproductives with non-developed ovaries and testes had a large amount of gut protists and well-expanded hindguts in an incipient colony. On the other hand, a small amount of gut protists and reduced hindguts were observed in the primary reproductives with well-developed ovaries and testes in a mature colony (400 days after colony foundation). Secondary reproductives collected from field colonies rarely had gut protists while workers and soldiers had a large amount of gut protists. Therefore, gut symbionts are harbored in non-active reproductive castes (alates and primary reproductives in incipient colonies) and sterile castes (workers and soldiers) rather than active reproductive castes (primary and secondary reproductives in mature colonies). The reduction of hindgut size related to the disappearance of gut microbes ensures space for reproductive maturation, suggesting that the maintenance of gut symbionts works as a suppressive factor of reproduction during the course of termite evolution.

Structure and function of the large pronotal horn of the sand-living anthicid beetle *Mecynotarsus tenuipes*

Kosei Hashimoto[1], Fumio Hayashi[2]

[1]Tokyo Metropolitan University, Japan, [2]Tokyo Metropolitan University, Japan

Large insect horns function as antipredator armaments, digging implements, and intraspecific combat weapons. The sand-living anthicid beetle Mecynotarsus tenuipes possesses a large horn on the pronotum. Allometric relationships between body size and horn size did not show a slope of more than 1 or sexual dimorphism, suggesting another function of the horn function other than sexual selection via combat. Behavioral observation of individuals using a micro-video camera indicated that the horn is used to dig and move forward in loose sand. Only the horned M. tenuipes could dig into the sand, in contrast to the hornless anthicid beetles Stricticollis valgipes and Clavicollis fugiens, which could not dig. When moving in sand, M. tenuipes joins its pronotal horn and head to form a conical shape, with which it pierces into the sand. Then, it opens its horn and head outward to create a space in the sand for forward motion. Although it can dig deep into sand by repeating these behaviors sequentially, digging speed tends to slow with depth, probably because the weight of the substrate increases.

Effect of global warming on occurrence of the maize orange leafhopper, *Cicadulina bipunctata*

Keiichiro Matsukura[1], Kazuhiro Yoshida[2], Masaya Matsumura[3]

[1]NARO Kyushu Okinawa Agricultural Research Center, Japan, [2]NARO Kyushu Okinawa Agricultural Research Center, Japan, [3]NARO Kyushu Okinawa Agricultural Research Center, Japan

The maize orange leafhopper, Cicadulina bipunctata is a serious pest of forage maize, causing maize wallaby ear symptom. This insect is originally distributed in tropical and sub-tropical regions in Africa, India and Southeast Asian countries; however its distribution has expanded to southern part of Japan since 1990s probably because of global warming. We examined effects of climatic factors (temperature, precipitation and sunlight) on the occurrence of C. bipunctata. Seasonal occurrence of adult C. bipunctata in a census field from July to August, when forage maize was most susceptible to the pest, could be described by a simple exponential function with two parameter: estimated density of C. bipunctata on 1 July (N0) and intrinsic rate of natural increase (r) for each year. Forward stepwise multiple regression analysis using seasonal occurrence data from 2004 to 2009 detected positive contributions of average temperatures in the previous December and February and a negative contribution of total precipitation during the previous winter to N0. The analysis also indicated that average temperature in July of the current year and N0 contributed positively and negatively to r, respectively. These results indicated that high temperatures and little precipitation during winter and high temperatures in early summer induced high occurrence of C. bipunctata in summer. A prediction model based on these factors supported the actual seasonal occurrence in 2010, suggesting that this prediction model is applicable to C. bipunctata forecasting.

Males kill their mating partner in a mass-reared population of the sweetpotato weevil *Cylas formicarius*

Keiko Shiromoto[1], Norikuni Kumano[2], Takashi Kuriwada[3], Tadashi Takizawa[4], Tetsuya Toyosato[5], Dai Haraguchi[6]

[1]Okinawa Prefectural Plant Protection Center, Japan, [2]Okinawa Prefectural Plant Protection Center, Japan, [3]National Agriculture and Food Research Organization, Kyushu Okinawa Agricultural Research Center, Japan, [4]Okinawa Prefectural Plant Protection Center, Japan, [5]Okinawa Prefectural Plant Protection Center, Japan, [6]Okinawa Prefectural Agricultural Research Center, Japan

Variation in mating opportunity often involves evolutionary change due to male manipulation during mating to assure paternity. If the female mating system changes to polyandry, the males would change the mating traits and/or mating behaviors. In an eradication program for using a sterile insect technique of the sweetpotato weevil, Cylas formicarius, in Okinawa, Japan, the weevils have been mass-reared artificially for over 90 generations. In this weevil, females do not secrete the sex pheromone after her first mating and thus the females will be monandry in the field condition. However, under the high-density such as the mass-rearing conditions, females could not avoid mating by many males after her first mating, and males can adopt several manipulations to avoid the risk of sperm competition. To avoid the remating for females, the mating will be the cost for females caused by the male inhibitions of female remating and the manipulative traits of mass-reared males will have been evolved; therefore we examined the effect of the mating with mass-reared males on female fitness. In the results, we found that some of mass-reared males killed their mating partner. Furthermore, we also found that the ejaculated semen of some mass-reared males reduced the female longevity by injecting male genital extracts into virgin female abdomens. We discuss adaptive significant of the results and paternity assurance of these traits with the males reduced the female longevity.

SEASONAL MONITORING OF THE INCIDENCE AND FLIGHT ACTIVITY OF THE GROUNDNUT LEAF MINER (*APPROAEREMA* SPP.) IN 5 SITES IN SOUTH AFRICA

Makhosi Buthelezi[1], Godfrey Zharare[2], Desmond Conlong[3]

[1]Mangosuthu University of Technology, South Africa, [2]University of Zululand, South Africa, [3]South African Sugarcane Research Institute, South Africa

Groundnut leaf miner (GLM) (Approarema spp.) is a relatively new pest on the African continent. In South Africa, it was first noted in 2000, and has since spread over the entire groundnut production areas of the country. A study was conducted in which the infestation of GLM in groundnut and the GLM flight activity were monitored from November 2010 to February 2012 at Bhekabantu, Manguzi, Nelspruit, Brits and Vaalharts. The flight activity was monitored using pheromone traps and the infestation on groundnut was monitored by scouting in a two-planting date experiment in two seasons (November 2010 and January 2011 in first season and in November 2011 and January 2012 in the second season). Additionally, a plant-host preference experiment was conducted in the 2011-2012 season, in which infestation of GLM was monitored on, groundnut, soybean, lucerne, pigeon pea and lablab, at five sites. Vaalharts had the most male GLM captured (42%) followed by Nelspruit with 31%, Manguzi 12%, Bhekabantu 10% and Brits 5%. The highest male peak capture in all the sites was between January and April. Males were caught throughout the year but the numbers were low in winter. Pest infestation on groundnut was late, occurring only 5 or more weeks after crop emergence. Soybean had the highest infestation rate followed by groundnut at all sites. Infestation on Pigeon pea was very low occurring on one to 5 plants per site. Lucerne was scarcely attacked by the pest. Infestation by GLM was not observed on lablab at all sites.

Predicting the effect of climate change on community structure and function: an assessment using grassland thrips

Matthew Binns[1], David Warton[2], Heloise Gibb[3], Nigel Andrew[4]

[1]University of New England, Australia, [2]University of New South Wales, Australia, [3]La Trobe University, Australia, [4]University of New England, Australia

Predicting how an ecosystem will respond to changes in climate is important when considering how to manage an area to reduce biodiversity loss. A common approach is to collect species abundance data from various climates, fit a model and use that to predict abundances under future climate scenarios. We will extend this idea by using recent developments in multivariate statistical modelling to predict how large communities will respond to climate change. This approach will provide more information than simply fitting separate models to each species, as extra power will be given to rare species predictions and we will be able to better assess interactions between species responses. In addition, a recently developed forth corner modelling technique will be used with morphology data to determine why particular species or individuals would respond the way they do. This will also test the idea that an assessment of trait diversity within a community can be more important that the species composition. For this assessment we are assessing Thysanoptera communities associated with Themeda australis dominated grasslands. The use of this host plant also provides the opportunity to assess the importance of ploidy in terms of structuring insect-plant interactions.

Adaptive significance of homing behavior in male scoliid wasps (Hymenoptera: Scoliidae)

Soichiro Tani[1], Takatoshi Ueno[2]

[1]Kyushu University, Japan, [2]Kyushu University, Japan

Homing and site fidelity are widely known for social and nesting Hymenoptera. However, such habits of non-nesting Hymenoptera, especially in males, have rarely been studied. We focused on the homing and site fidelity in males of scoliid wasps, which are non-nesting ectoparasitoids of scarabaeid grubs. We observed the males patrolling around a small specific area, and considered that they could show strong site fidelity and homing to return to their own patrol area. Accordingly, we addressed the following questions: (1) Do males have site fidelity and return to their own patrol area from an artificially displaced area? (2) Is the patrolling area a birthplace of the males and females? (3) Why does a male persist in a birthplace? (4) Do males repeatedly move between feeding and patrolling areas? Basing on a series of field experiments, we suggest that the male wasps have homing ability and strong site fidelity to their own patrol area, and propose that this homing ability has evolved in a specific condition that males need to stay in a birthplace for mate search and to move between feeding and patrolling areas. Unlike the case in the other social and nesting Hymenoptera, homing behavior in males of non-nesting Hymenoptera should have a different evolutionary background. Therefore, the finding of homing behavior in male scoliids and clarification of its adaptive significance are important to reveal the evolution of homing behavior in the Hymenoptera.

Plant host differences in the genus *Cossus* (Cossidae): insights from mechanical tests and molecular phylogeny

Luis Fredd Leonardo Vergara Montalvo[1], R. Craig Everroad[2], Guadalupe Andraca[3], Jun Kikuchi[4], Hiroshi Makihara[5]

[1]RIKEN, Japan, [2]RIKEN, Japan, [3]UNAM, Mexico, [4]RIKEN, Japan, [5]FFPRI, Japan

Larvae of the family Cossidae are mostly associated with trees. Cossus redtenbacheri (Hammerschmidt) is exceptional in this family because its larvae live in agave. Two approaches were followed to better characterize this host difference. First, a mechanical test was performed to evaluate the gallery making ability of larvae transferred to non-natural hosts of differing tissue hardness. Second, the first molecular evolutionary analysis of C. redtenbacheri was performed to assess its relationship with selected wood-feeding Cossidae species. This phylogenetic reconstruction was based on partial sequences of mitochondrial cytochrome c oxidase subunit 1. The results show that the host difference is not due to mechanical constraints. Phylogenetically, the agave-feeding phenotype is confirmed as a derived character within the genus Cossus. The possibility and type of ecological factors that may explain the host specialization of C. redtenbacheri are discussed.

Elucidating factors by which *Orius* spp. is attracted and arrested to Okra

Hojun Rim[1], Masayoshi Uefune[2], Rika Ozawa[3], Akio Nakano[4], Junji Takabayashi[5]

[1]Kyoto University, Japan, [2]Kyoto University, Japan, [3]Kyoto University, Japan, [4]Tokushima Agriculture, Forestry, Fishery Technology Support Center, Japan, [5]Kyoto University, Japan

Under field conditions, predatory bugs Orius spp. are often found at buds of Okra plants, Hibiscus esculentus, but not on leaves, even though the buds are not infested by their prey. The number of Orius spp. at buds is different in three cultivars of Okra (Marumi, Beni and Early five). We investigated how Orius spp. were attracted and arrested at Okra buds by using Orius strigicollis and two cultivars, Beni and Marumi. Bioassays using a Y-tube olfactometer revealed that adult females of O. strigicollis were attracted to volatiles from Marumi buds. Volatiles from Beni buds tended to attract adult females, though it was not statistically significant. Adult male O. strigicollis were not attracted to volatiles from Okra buds of both cultivars. In the rearing vial, when offered buds of Marumi or Beni, Orius survived longer than control (no buds in the vial). In contrast, when offered leaves of Marumi or Beni in the rearing vial, longevity of O. strigicollis was not significantly different from that in control (no leaves in the vial). Headspace analyses of Marumi and Beni buds showed that linalool, β-ocimene, and 3-Hexen-1-ol acetate were the major compounds. Bioassays using these compounds to clarify the active principals that attract and/or arrest O. strigicollis at buds is now under way.

Historical fires on grasslands in central Japan and its causation to distributions of grassland species of bumblebees and endangered butterflies

Takeshi Suka[1], Hiroyuki Tanaka[2], Atsushi Ushimaru[3], Kei Uchida[4], Takakazu Yumoto[5]

[1]Nagano Environmental Conservation Research Institute, Japan, [2]Kyoto University, Japan, [3]Kobe University, Japan, [4]Kobe University, Japan, [5]Kyoto University, Japan

The warm and humid climate causes ecological succession of most vegetation to forest in Japan. However, this view of the Japanese vegetation is on the assumption that human disturbance is absent. In fact, grassland species of plants and insects have survived in semi-natural grasslands from the time of the glacial periods until today. Tremendous reduction of semi-natural grasslands during the 20th century in Japan caused crucial threat to the grassland species. Many of these species are considered to be relics since glacial periods that had expanded from the Asian continent probably through the Korean Peninsula. To clarify the significance of the inferred human influence on the maintenance of habitats for these species, the history of vegetation, archaeology and Japanese history are reviewed and statistical analyses were conducted using data from recent and present insect distributions in Nagano Prefecture, central mountainous area of Japan. Existence of a black soil, called 'kuroboku', indicates the locations of the past semi-natural grasslands caused by fire since the Jomon era (the early Holocene). Many of the ruins of the Jomon era are assembled in the areas of black soil and pasture fields since the ancient age had often overlapped with those areas. Statistical analyses using generalized linear model (GLM) exhibited that distribution of endangered grassland species of bumblebees (Bombus spp.) and endangered grassland butterflies including Shijimiaeoides divinus barine coincide with the areas of the black soil. It suggests that the usage of fires by humans had historically provided continual habitats for the grassland species.

The mating system using volatile and substrate-born sex pheromones in a polyphagous solitary parasitoid wasp, Itoplectis naranyae

Hiroki Itadani[1], Takatoshi Ueno[2]

[1]Kyushu University, Japan, [2]Kyushu University, Japan

Although volatile or substrate-born sex pheromones are known in some parasitoid wasps, the detail process of the mate search by parasitoid wasps has rarely been examined. The parasitoid wasp Itoplectis naranyae is distributed in Japan and the other East Asia and found in rice paddies and grass fields covered mainly by Poaceae plants. I. naranyae parasitizes variety kinds of lepidopteran pupae including rice pests. Because of solitary polyphagous parasitizing style, each sex is scattered in the environment and the mate search would be difficult in this parasitoid. However, the mating rate of wild females was shown 100%. The percentage suggested the existence of a mating system to ensure successful sexual encounter. In the previous study, we have demonstrated the existence of volatile sex pheromones secreted by the parasitoid, but the attractiveness was not enough in the field. Thus we suspected that volatile sex pheromones were not the sole cue used in the mate search and conducted a series of laboratory experiments to examine other cues involved. We found that male I. naranyae showed longer antennal sweep duration to glass walked by virgin than by mated females. Additionally, males presented more wing vibration frequency on the glass walked by young than old females. The results indicated that I. naranyae used substrate-born sex pheromones as another cue for mate search. Thus, I. naranyae uses two different types of sex pheromones to overcome difficulty in mate location. The combination of two different cues would ensure successful sexual encounter.

Effect of bush burning on the egg parasitoid, *Trichogramma chilonis* Ishii (Hymenoptera: Trichogrammatidae) of the endangered butterfly, Shijimiaeoides divinus barine (Leech) (Lepidoptera: Lycaenidae)

Keiko Koda[1], Hiroshi Nakamura[2]

[1]*Shinshu University, Japan,* [2]*Shinshu University, Japan*

The large shijimi blue, Shijimiaeoides divinus (Fixsen), is a grassland lycaenid butterfly, which is distributed in Japan, the Korean Peninsula, Northeastern China and the Southern Amur region. This butterfly was designated an Endangered Species by the Ministry of the Environment of Japan. Only small populations of the subspecies S. divinus barine remain in limited areas of Nagano Prefecture in Japan. The volunteer organization has been in active to recover the natural population of this butterfly by the method of releasing pupae. However, the natural population was not recovered. We clarified that the egg parasitoid, Trichogramma chilonis was an important mortality factor of the egg stage of S. divinus barine. Bush burning experiment was carried out in Azumino City, Nagano Prefecture on March 29, 2009 in order to verify the effect of bush burning on the egg parasitoid. Immediately after bush burning, a cage was set up in the bush burning area and the control area respectively. The percentage of parasitism inside the cage was 2.3% in the bush burning area and 30.3% in the control area ($P<0.01$). It was given as a conclusion that the bush burning had an effect on parasitism of T. chilonis on S. divinus barine eggs. In Alps Azumino Natural Government Park in Azumino City, bush burning has become to be performed by the results of our researches every year. As a result, S.divinus barine adults were recovered in 2011 after the 15 years' separation in this area.

Physiological response of strawberry (Fragaria x ananassa Duch. cv. 'Yunia Smuds') to spider mite (*Tetranychus atlanticus* McGregor, 1941) feeding

Alexey Baikov[1], Alena Kvitka[2], Sergey Yakovlevich Popov[3], Mikhail Solntsev[4], Alexander Tikhonov[5]

[1]All-Russian Research Institute of Vegetable Breeding and Seed Production, Russia, [2]Russian Timiryazev State Agrarian University, Russia, [3]Russian Timiryazev State Agrarian University, Russia, [4]M.V. Lomonosov Moscow State University, Russia, [5]M.V. Lomonosov Moscow State University, Russia

Plants were grown in a greenhouse at 20-24ºC, 65-85% RH, and a photoperiod of 16:8 (L:D) h. Each leaf was infested with 10 spider mite protonymphs. Population dynamics were counted on 2th, 9th and 16th day after the infestation. These data were used for calculation of mite-days. There were equal to 3,9±0,3, 66,2±6,9 and 86,8±20,7 for 2, 9 and 16 days, correspondingly. Non-photochemical quenching of chlorophyll fluorescence (NPQ) after 2 days was the same as in the control. On 9th and 16th days NPQ consistently increased as compared with controls. The thermoluminescence intensity (TL) in the temperature range from -40 to +30ºC for 2 and 9 days was slightly lower than in controls, and significantly decreased after 16 days. Although measurements of fluorescence parameters indicated a disruption of photosynthetic apparatus, chlorophyll content was not affected by spider mite feeding. Mite feeding caused a mechanical injury that was restricted to the spongy mesophyll with minimal damage to the uppermost palisade layer. This may explain the lack of relationship between chlorophyll content and injury. In injured leaves the intensity of the high-temperature TL (≥ 60ºC) after two days was the same as in the control, after 9 days intensity increased as compared with the control and remained the same on the 16th day. The growth of high-temperature TL may indicate a partial degradation of membrane lipids during oxidative stress. This effect may be due to reduction in leaf gas exchange parameters, especially CO2 fixation with the resultant generation of ROS.

Changes of the land use and decline of the endangered butterfly, *Shijimiaeoides divinus barine* in Azumino, Japan

Hiroshi Nakamura[1], Keiko Koda[2], Takeshi Suka[3]

[1]Shinshu University, Japan, [2]Shinshu University, Japan, [3]Nagano Environmental Conservation Research Institute, Japan

The large shijimi blue, Shijimiaeoides divinus barine is distributed in limited areas of Nagano Prefecture in Japan at present. It has been designated an Endangered Species by the Ministry of the Environment of Japan. A large population of this butterfly was observed till 1960. However, the population of S. divinus barine decreased with the changes of the management methods (mowing and bush burning) of inhabitant area. We clarified that the bush the burning had a good effect on survival of S. divinus barine. When did bush burning begin in Japan? The andosol which was formed by the bush burning in the Jomon period (BC10000-BC3000) is widely distributed in Nagano Prefecture. It is known that the distribution areas of S. divinus barine overlapped the andosol and the imperial pastures (about AD900). The semi-natural grassland which is suited to S. divinus barine has been maintained from the Jomon period by pasturage or bush burning in Nagano Prefecture. However, after the Edo period, the paddy field was reclaimed in Azumino, and the pastures were lost (about AD1800). Was S.divinus barine exterminated? Sophora flavescens, the host plant of this butterfly, was planted in ridges of a rice field and the bank of the irrigation canal as a herb. Mowing and bush burning were performed periodically there. Thus, the habitat of S.divinus barine has been maintained. However, the land improvement enterprise was undertaken around from 1962. Sem-natural grassland vegetations including S. flavescens were lost and S.divinus barine can live has disappeared.

Effect of grazing intensity on species diversity of butterfly communities

Kouhei Murata[1], Asana Matsuura[2]

[1]Tokai University, Japan, [2]Tokai University, Japan

We conducted route census surveys on butterfly communities in the grasslands under different grazing intensities on the volcanic slopes of Mt. Aso, Japan. At the study sites, the semi-natural grassland underwent routine burning every spring. The results obtained are summarized as follows: (1) Sixty-four species assigned to five families were recorded. (2) Ten "rare species" nominated in the "red list" were recorded. (3) Grassland species, Shijimiaeoides divinus asonis and Colias erate poliographys. And forest species. Celastrina argiolus labonides, Ypthima argus and, Eurema mandarina were abundant. (4) More species were found in the non-grazing site (site NG) than in the customary grazing site (site CG), and more forest species were found in the site NG than in the site CG. (5) Shimpson's index of diversity (1-λ) was higher in the site NG than in the sites CG. (6) S. divinus asonis was the most abundant species at the site CG. (7) Shimpson's index of diversity (1-λ) decreased as the grazing intensity increased. (8) Grazing intensity didn't affect the number of rare grassland species. The number of rare forest species at NG was the highest among the four study sites. (9) The ratio of S. divinus asonis to all butterflies was about 90 % in the sites NG, LG, and CG. In conclusion, mixture of grasslands under various grazing intensity may have a benefit for the maintenance of diversity of butterfly fauna. Especially, grasslands maintained without grazing

Effects of jasmonate and salicylate induced defense in wheat on grain aphid, *Sitobion avenae* (Hemiptera: Aphididae)

Hehe Cao[1], Tongxian Liu[2]

[1]*State Key Laboratory of Crop Stress Biology on the Arid Areas, China,* [2]*State Key Laboratory of Crop Stress Biology on the Arid Areas, China*

Jasmonate and salicylate-mediated signaling pathways play significant roles in induced plant defenses. We studied biochemical responses and effects on grain aphid, Sitobion avenae (Fabricius) when exogenous applied methyl jasmonic acid (MeJA) and salicylic acid (SA) on wheat. Application of MeJA significantly increased levels of polyphenol oxidase (PPO) and proteinase inhibitor 1, 2 and 6 days after treatment. In two choice tests, adult aphids prefer untreated leaves to MeJA- or SA-treated leaves, and the weight of apterous adult aphids reared on MeJA treated seedlings were reduced significantly as compared with those on untreated seedlings. Electrical penetration graph (EPG), however, showed that the stylet activities of aphids had similar patterns on all treated plants. Total probing time and phloem phase time on MeJA- and SA-treated plants were not different from those on untreated plants. Duration of the aphid's first probe on MeJA treated plants was significantly shorter and the aphid's salivation period phase on SA treated plant was longer as compared with those on other plants. These findings advance the knowledge of the effects of JA-dependent and SA-dependent defenses in wheat on phloem-feeding insects. Our results suggest that both MeJA and SA applied to wheat seedlings negatively influenced aphid colonization processes.

Phenotypic and genetic differences among exotic herb *Solidago altissima*: how do they respond to reassociation with the exotic insects ?

Yuzu Sakata[1], Takayuki Ohgushi[2], Yoshino Ando[3], Yuji Isagi[4]

[1]Kyoto University, Japan, [2]Kyoto University, Japan, [3]Kyoto University, Japan, [4]Kyoto University, Japan

Introduced species often quickly change in terms of genetic variation and phenotypic traits due to adaptive evolution. However, the time scale responding to the trait change after invasion is poorly explored. The recent expansion of an invasive herbivorous insect Corythuca marmorata, which was firstly recorded in 2000 in Japan, of the exotic plant Solidago altissima provides an opportunity to test the potential of the selective impacts of this herbivore on plant defensive traits. Because the invasion process of C. marmorata differs geographically in Japan, the defensive traits of S. altissima may have locally evolved. We focused on the geographic variation of the insect species, abundance, and genetic and phenotypic differences among S. altissima populations in a wide range of Japan. The averaged damage by C. marmorata was lower in populations where C. marmorata was initially introduced than the populations in the recent expanded range. Moreover, the S. altissima populations were exclusively hexaploid, although diploid, tetraploid, and hexaploid are reported in its native range. These findings suggest that the defensive traits may have been subjected to natural selection differently in local populations in response to local biotic environments in a short time scale, providing a new insight to understanding the rapid adaptation of introduced plants in response to community composition of insect herbivores in a new habitat.

A survey on oviposition behavior of *Tirchogramma brassicae*

Hossein Kishani Farahani[1], Ahmad Ashouri[2], Martin Shapiro[3], Seyed Hossein Goldansaz[4], Akbar Golshani[5], Yasaman Moghaddasi[6]

[1]University of Tehran, Iran, [2]University of Tehran, Iran, [3]California state university, U.S.A., [4]University of Tehran, Iran, [5]university of Tehran, Iran, [6]University of Tehran, Iran

Several studies have proven that T. brassicae is the most dominant species in Iran with most distribution. Considering the importance of studying oviposition behavior and spent times during these behaviors and widespread use of T. brassicae in biological control programs this study was conducted to study this behavior of sexual T. brassicae. Studying of behavior was conducted under controlled condition: 25±1°C, 50±10 % RH and 16:8 L:D. Individual Trichogramma females were presented with egg patches consisting of 100 host eggs glued with water on to a 5×5 cm white cardboard square with different host quality (100 fresh and old host eggs) separately. The host eggs were separated by a distance of 5 mm. A sequence of six behavioral events was used to monitor host use by the Trichogramma females. Spent time for oviposition on each fresh egg was 70±0.45 S, while this amount on old eggs was 73±0.61 s. Observed acceptance time for each fresh egg was 15±0.29 s but this time on old eggs was 14 ± 0.44 s. Rejection time of each fresh egg was 6±0.91 s and this parameter was 7±0.77 for each old egg.

Odor learning has been studied on large number of hymenopteran species and documented for nearly 36 species of Hymenoptera. According to several studies T.brassicae is the most dominant species among Trichogramma wasps in Iran. Thelytoky has been observed base on Wolbachia infection in this species. This study was carried out to show learning ability and memory duration of wolbachia infected T.brassicae .Wasps culture was carried out in controlled condition, 25±1°C, 70±10% RH and 16:8 L: D. Twenty naive one day old wasp were introduced to odor tanks and one hundred one day old flour moth egg were exposed to these wasps for 5 hours and olfactory response of these wasps were observed in Y maze olfactometer. According to our results learning ability of this wasp was proven, maximum olfactory response was recorded till 12 hours and continued till 24 hours. Maximum memory duration period of this wasp was 24 hours after exposing to odor.

Endophytic bacteria associated to sharpshooters, insect vector of *Xylella fastidiosa*: Potential of symbiotic control

Paulo Teixeira Lacava[1], Claudia Santos Gai[2], Antonio Sergio Ferreira Filho[3], Welington Luiz Araujo[4], Maria Carolina Quecine[5], Andrea Cristina Bogas[6], Priscilla Barros Rossetto[7], Joao Lucio Azevedo[8]

[1]Federal University Of Alfenas, Brazil, [2]University of Sao Paulo - ESALQ, Brazil, [3]University of Passo Fundo, Passo Fundo, Brazil, [4]University Of Sao Paulo - USP, Brazil, [5]University of Sao Paulo - ESALQ, Brazil, [6]University of Sao Paulo - ESALQ, Brazil, [7]University of Sao Paulo - ESALQ, Brazil, [8]University of Sao Paulo - ESALQ, Brazil

Xylella fastidiosa causes citrus variegated chlorosis (CVC) disease, resulting in significant production losses in the citrus industry. X. fastidiosa is transmitted by species of sharpshooters. We identified bacterial communities associated with the heads of surface-sterilized insect vectors of X. fastidiosa. Bacteria were isolated and analyzed by amplified ribosomal DNA restriction analysis and sequencing, revealing the presence of the well-known citrus endophytes Methylobacterium spp. and Curtobacterium spp. Paratransgenics, also called symbiotic control, is a new strategy that consists of genetic alteration in symbiotic microorganisms and the reintroduction of them into their original niche. The key to symbiotic control is finding microorganism candidates that are associated with the target plant-pathogen or pest. Based on the premise of symbiotic control, we genetically modified the citrus endophytic bacterium Methylobacterium extorquens and evaluated its capacity to colonize a model plant and its interaction with X. fastidiosa. This Methylobacterium strain was genetically transformed to express heterologous Green Fluorescent Protein (GFP) and an endoglucanase A (EglA), generating the mutant strains ARGFP and AREglA. By fluorescence microscopy, it was shown that ARGFP was able to colonize xylem vessels of host plant. Using scanning electron microscopy, it was observed that AREglA and X. fastidiosa may co-inhabit the xylem vessels of host plant and appeared to cause a decrease in biofilm formation. AREglA stimulated the production of resistance protein, catalase, in the inoculated plants. Our results provide an enhanced understanding of the M. extorquens and X. fastidiosa interaction, suggesting the application of endophytes as an agent of symbiotic control.

Take-off behavior of *Cnaphalocrocis medinalis* (Guenee) (Lepidoptera: Pyralidae) in field conditions and it's relation to temperature, illuminance and wind speed

Fan Yang[1], Xiaoxi Zhang[2], Baoping Zhai[3]
[1]Nanjing Agricultural University, China, [2]Nanjing Agricultural University, China, [3]Nanjing Agricultural University, China

The aerial flight process of migrating insects roughly consists of three stages: taking-off, navigation and landing. Taking-off so played an important role as the initiation of migration. In this study we observed the take-off behavior of Cnaphalocrocis medinalis (Guenee) for summer migration both in rice field of natural state and a climate chamber. And possible relationships with certain environmental factors including ambient temperature, light intensity and wind speed were analyzed. The whole process of take-off behavior of C. medinalis occurred in 20 - 40 minutes after sunset and reached peak period at the ending of evening twilight. There were no individuals taking-off before sunset. Occurrence of the take-off behavior needed the triggering of optimum light intensity that ranged from 0.1 to 10 lx. We also show that ambient temperature and wind speed have an influence on the flight and landing behavior of C. medinalis. The ovarian development showed significant difference between emigrants and retentions, which mean that the oogenesis-flight syndrome occurred in its first long distance migration.

Evaluation of meridic diets for rearing *Scyphophorus acupunctatus* (Coleoptera: Curculionidae)

Ma. Elena Valdes-Estrada[1], Lucila Aldana-Llanos[2], Alfredo Jimenez-Perez[3], Mirna Gutierrez-Ochoa[4], Maria C. Hernandez-Reyes[5]

[1]Centro de Desarrollo de Productos Bioticos, Mexico, [2]Centro de Desarrollo de Productos Bioticos, Mexico, [3]Centro de Desarrollo de Productos Bioticos, Mexico, [4]Centro de Desarrollo de Productos Bioticos, Mexico, [5]Centro de Desarrollo de Productos Bioticos, Mexico

The weevil, Scyphophorus acupunctatus Gyllenhall, is an important pest of Agave spp. and Mexican tuberose (Polianthes tuberosa L.). Larvae feed in the tuberose bulb forming galleries and complete their development within a cocoon from which the adult emerges. Damage is estimated to be 35 to 70% of adult plants. Copulation is carried out among the bulbs, where the female lays her eggs. We evaluated 4 diets; all diets included the following: agar, vitamins, sucrose, brewer's yeast, wheat bran, cholesterol, Wesson salt mixture, sorbic acid, ascorbic acid and methyl P-hydroxybenzoate. Three diets were supplemented with different amounts of tuberose host-plant bulb and one with jicama (Pachyrhizus erosus R. T. Clausen Urb.). The tuberose bulb was used as a control. All of the diets assayed were accepted by S. acupunctatus neonatal larvae. Larvae fed with the tuberose C diet had the lowest weight while those fed with the tuberose A and jicama had the highest weights. Total survival from larva to adult was significantly high on tuberose B and tuberose C diets, while total survival for the jicama diet was considerably lower and even less than in the control. Total larval + pupal development time in the 4 meridic diet were significantly longer than on the control. Insects feed on tuberose diets had larger fecundity, fertility and oviposition rate than those on the control. These results show that one of the tuberose diets is suitable for establishment of a lab colony.

Seed predation process of *Megastigmus transvaalensis* (Torymidae) in *Schinus terebinthifolius* (Anacardiaceae) in Brazil

Sergio Jansen[1], Simone Padua Teixeira[2], Rodrigo A. Santinelo Pereira[3]

[1]Universidade de Sao Paulo, Brazil, [2]Universidade de Sao Paulo, Brazil, [3]Universidade de Sao Paulo, Brazil

We studied larval biology and seed predation process of Megastigmus transvaalensis on four individuals of the dioecious tree Schinus terebinthifolius, between February-April 2011/2012. For this, we experimentally manipulated fruit age and wasp oviposition time. Previously the experiments, branches containing about 100 pistilate flowers were isolated with tissue bags before receptiveness. At anthesis, stigmas were manually pollinated using a fine paintbrush impregnated with pollen. When fruits attained the ideal size for oviposition, we introduced inside the tissue bags 20-30 female wasps obtained from other S. terebinthifolius individuals. We allowed wasps to oviposit for 48h. From last oviposition day we collected 30 fruits at 2-3 days intervals up to larvae have completed their development. We manually dissected 5 oviposited seeds, recorded the larva position inside the seed and measure its body length. Oviposition occurred in fruits aged 15-20 days, when plant embryo was at its cotyledonary stage. Egg was always deposited inside the nucellus. First larval stage (0.41±0.13mm, n=20; 4-7 days) began to feed on endosperm. Seed continued its growth and second larval stage (1.01±0.37mm, n=25; 8-9 days) attacked part of the integument, endosperm and occasionally the plant embryo. The third larval stage (3.42±0.98mm, n=40; 10-15 days) consumed the mature plant embryo and occupied most of the seed cavity. We showed that M. transvaalensis development is adjusted to exploit resources derived from the plant embryological processes. Financial support: S.J.G. FAPESP#09/10237-9. R.A.S.P. Different uses of plant semiochemicals in host location strategies of two "microtype" parasitoid flies

Ryoko Tabata Ichiki[1], Giang Thi Thu Ho[2], Eric Wajnberg[3], Yooichi Kainoh[4], Jun Tabata[5], Satoshi Nakamura[6]

[1]Japan International Research Center for Agricultural Sciences (JIRCAS), Japan, [2]Japan International Research Center for Agricultural Sciences (JIRCAS), Japan, [3]I.N.R.A., France, [4]University of Tsukuba, Japan, [5]National Institute for Agro-Environmental Sciences, Japan, [6]Japan International Research Center for Agricultural Sciences (JIRCAS), Japan

Some members of the Tachinidae (Diptera) deposit a large number of small eggs, termed "microtype" eggs, on the food plant of their herbivorous host. Parasitization becomes successful only when the host ingests these eggs. To increase the chance of hosts encountering the eggs, the microtype tachinids have to choose a suitable plant that harbors hosts and/or lay their eggs near the hosts. In the host location process, semiochemicals emitted by host-infested plants provide reliable cues to the tachinids. We investigated the behavioral response of two microtype tachinids, Pales pavida and Zenillia dolosa, in a wind tunnel with maize plants infested with a common host, the larvae of the noctuid moth Mythimna separata. Females of P. pavida showed a significantly higher rate of landing on M. separata-infested maize plants than on artificially damaged or intact plants. Z. dolosa landed on both the infested and artificially damaged plants with significantly higher rates than on intact maize plants. We also examined which part of the infested maize leaf induces oviposition. P. pavida deposited eggs on the margin of the leaf. In contrast, Z. dolosa intensively laid eggs around an area of host infestation or an artificially damaged spot. The eggs of P. pavida demonstrated parasitization ability over 15 days after they were deposited on plants, while the eggs of Z. dolosa did not survive more than 5 days after oviposition. Our data illustrate that each microtype tachinid employs a different host location strategy to increase the rate of parasitization success.

Trade-offs between pupal melanism and life-history traits in *Spodoptera exigua*

Mo Wang[1], Sisi Liu[2]

[1]Huazhong Agricultural University, China, [2]Huazhong Agricultural University, China

Insect melanism has interested biologists for long time, and its study integrates diverse classical branches of biology, including ecology, development, genetics and physiology. In this study, we established a homozygous melanic strain (SEM) with black pupae spontaneously occurring within a laboratory population (SEW) of Spodoptera exigua. Morphological photograghy showed that the SEM strain is globally melanism in the pupa stage but not in the egg and larval stages. After pupation, the SEM pupae gradually turn black, while the SEW pupae gradually turn yellow-brown, indicating that melanin over synthesizes in SEM. Life-table experiments indicate that the SEM strain has faster development in all life stages, heavier pupa weight, higher mating rate and fecundity, more mating time and accordingly higher net reproductive rate and population trend index. Single pair inbreeding and reciprocal crosses reveal that there is no reproductive isolation between the SEM and SEW strains, and the reciprocal crosses rate is significantly higher than intra-cross rate of SEW strain. The color of filial generation pupae are different from their parents, and the pupae of F1 progeny from ♀SEW×♂SEM are dark-brown while the pupae of F1 progeny from ♀SEM×♂SEW are light brown. These results illustrate that Spodoptera exigua pupal melanism is an advantageous mutation. The SEM strain will be a good model organism for study on the naturally variable genotypes with the phenotypes that affect fitness in Lepidoptera.

The effect of larval density on development of the coconut hispine beetle, *Brontispa longissima* (Gestro) (Coleoptera: Chrysomelidae)

Mika Murata[1], Dang Thi Dung[2], Shun-ichiro Takano[3], Ryoko Tabata Ichiki[4], Satoshi Nakamura[5]

[1]National Institute for Agro-Environmental Sciences, Japan, [2]Japan International Research Center for Agricultural Sciences (JIRCAS), Japan, [3]Japan International Research Center for Agricultural Sciences (JIRCAS), Japan, [4]Japan International Research Center for Agricultural Sciences (JIRCAS), Japan, [5]Japan International Research Center for Agricultural Sciences (JIRCAS), Japan

The coconut hispine beetle, Brontispa longissima is one of the most serious insect pests of the coconut palm, Cocos nucifera. This beetle is distributed in Southeast Asia, China, Japan, the Pacific Islands and Australia. Brontispa longissima shows aggregation in the field. To elucidate the effect of aggregation on larval developmental aspects, we examined the effects of larval density on various aspects of larval development and on survival rates. Recently we found that B. longissima was divided into two monophyletic clades by genetic analysis. Therefore, we also compared the results between two populations, from Ishigaki, Japan (ISH) and Papua New Guinea (PNG), which were representative of the two monophyletic clades of B. longissima. In both ISH and PNG, the larval developmental period was shorter and the survival rate higher with rearing under high density conditions than under isolated conditions. Similarly, fewer instars were required before pupation under high density conditions than under isolated conditions. Our study revealed that B. longissima developed better under high-density conditions, and the trends in the density effect were similar between two monophyletic clades.

Factors associated with damage to blueberry fruits by *Drosophila suzukii*

Hirotoshi Kinjo[1], Yasuhisa Kunimi[2], Takuya Ban[3], Madoka Nakai[4]

[1]Tokyo university of agriculture and technology, Japan, [2]Tokyo university of agriculture and technology, Japan, [3]Tokyo university of agriculture and technology, Japan, [4]Tokyo university of agriculture and technology, Japan

Drosophila suzukii is a pest of thin-skinned fruits including strawberry, blueberry and cherry. Blueberry was introduced into Japan in the 1980s, and severe economic losses attributable to D. suzukii were first reported in 2002. D. suzukii occurs in July and September around Tokyo, but is absent during August. One of the two major species, Highbush blueberry (Vaccinium corymbosum L), harvested in July, can receive serious damage from D. suzukii but the other species, Rabbiteye blueberry (Vaccinium virgatum Aiton), harvested in August, suffers little damage. Since the reasons for this difference in damage are not clear, the objective of this study was to elucidate whether temperature and blueberry variety influenced the extent of damage by D. suzukii to blueberry cultivation. Oviposition by D. suzukii females in berries of different varieties and fruit firmness was examined in the laboratory. More eggs tended to be laid in berries of cultivars having soft fruits than having hard fruits. Larval development and oviposition of D. suzukii at different temperatures were examined. Above 31 °C, larval development was prolonged and adult eclosion was inhibited. When adults mated at 25°C, 28 °C and 31°C for 4 days, the numbers of oviposited eggs were lower than those at 25 °C, and the hatching rate at 31°C was lower than those at 25 °C and 28°C. Thus, Rabbiteye blueberries appear to escape serious damage by D. suzukii because the harvest season coincides with peak temperatures in August, when larval development and adult reproductive activity are likely to be suppressed.

Aster Yellows phytoplasma strain Witches Broom alters plant development to manipulate plant-insect interactions

Allyson Marie MacLean[1], Heather Kingdom[2], Akiko Sugio[3], Saskia Hogenhout[4]

[1]John Innes Centre, United Kingdom, [2]John Innes Centre, United Kingdom, [3]John Innes Centre, United Kingdom, [4]John Innes Centre, United Kingdom

Phytoplasma are pathogens that cause disease in a wide range of agricultural plants. These bacteria have a unique life cycle that involves the colonization of eukaryotic hosts belonging to two kingdoms, namely plants (Plantae) and insects (Animalia). Phytoplasma are transmitted to plants by phloem-feeding insects, including planthoppers, leafhoppers, and psyllids. Naive (uninfected) insects acquire the bacteria whilst feeding from infected plants, and remain infected for life. Accordingly, phytoplasma fitness is strongly influenced by the interactions that occur between its plant and insect hosts. Aster Yellows phytoplasma strain Witches Broom (AY-WB) can infect a broad range of plants, including Arabidopsis, and is transmitted by the aster leafhopper Macrosteles quadrilineatus. Infected plants exhibit symptoms that reflect alterations in development, including the increased production of stems ('witches broom' phenotype) and growth of green, leaf-like flowers. AY-WB-infected Arabidopsis plants also become better hosts to support the reproduction of M. quadrilineatus: leafhoppers produce approximately 60% more progeny on AY-WB-infected plants compared to healthy controls. Furthermore, the specialist corn leafhopper Dalbulus maidis survives longer and produces eggs when caged on AY-WB-infected Arabidopsis, whereas D. maidis will not oviposit on healthy plants. Our central hypothesis is that AY-WB secretes proteinaceous effectors that target host processes relevant to defence and development. We have characterized two effectors produced by AY-WB, SAP11 and SAP54, which elicit phenotypes when expressed in Arabidopsis that resemble symptoms of AY-WB infection. We discuss herein how these effectors may hijack plant development to increase plant-insect interactions to the benefit of the phytoplasma.

Differential pesticide susceptibility explains replacement of *Neoseiulus womersleyi* by *N. californicus* in Japanese pear orchards

Masumi Hanawa[1], Koichi Goka[2], Tetsuo Gotoh[3]

[1]Ibaraki University, Japan, [2]National Institute for Environmental Studies, Japan, [3]Ibaraki University, Japan

Neoseiulus californicus and N. womersleyi are important natural enemies of spider mites. In 1963, N. californicus was first collected in Japan, but no further collections were made until the 1980s. Since the 1990s, the indigenous N. californicus strain is abundant and found on a variety of deciduous trees and weeds, and it has replaced N. womersleyi in many conventional Japanese pear orchards in central and southeastern Japan. This increase of N. californicus in Japan precedes the use of a commercial strain of N. californicus (Spical®), because this strain has not been used in Japanese greenhouses and fields before 2003. In this study, we tested the hypothesis that species replacement is due to differences between N. californicus and N. womersleyi in susceptibility to agricultural chemicals used before and after 1990: N. californicus is highly susceptible to chemicals used before 1990 but less susceptible to those used after 1990, and vise versa for N. womersleyi. We compared the susceptibility of N. californicus and N. womersleyi to 22 chemicals (11 insecticides, six acaricides and five fungicides) used before and after 1990. Susceptibility of N. californicus to chemicals used before 1990 was high. In contrast, N. californicus showed lower susceptibility to some chemicals used after 1990, especially to neonicotinoid pesticides, which had significantly lower effects when compared with N. womersleyi. These results suggest that difference in susceptibility to neonicotinoid pesticides is one of the possible factors influencing species replacement from N. womersleyi to N. californicus in Japan.

Stage-specific defensive strategies of three mantid species, *Tenodera aridifolia, Hierodula patellifera*, and *Statilia maculata*, against a natural enemy

Hiroshi Watanabe[1], Eizi Yano[2]

[1]Kinki University, Japan, [2]Kinki University, Japan

Three mantid species, Tenodera aridifolia (Stoll), Hierodura patellifera (Serville), and Statilia maculata Thunberg, of varying body sizes and habitats, exhibited defensive reactions when faced with a natural enemy, the Japanese skink [Takydromus tachydromoides (Schlegel)]. Defensive reactions were analyzed as primary or secondary defenses for all developmental stages. Of the primary defenses, the cryptic reaction was the main defensive reaction: mantids lowered the prothorax and simultaneously stretched the prothoracic legs, the antennae were arranged anteriorly, and the abdomen was sometimes extended posteriorly. The frequency of the subcryptic reaction as a primary defense tended to increase with more advanced developmental stage. The primary defensive strategy switched at a specific developmental stage and also depended on the distance between a prey mantid and the natural enemy. In some instars, T. aridifolia and H. patellifera displayed a cryptic reaction when the mantid-foe distance was long, whereas they displayed a subcryptic reaction when the mantid-foe distance was short. However, S maculata did not switch defense strategies based on the mantid?foe distance. The secondary defenses of young instar nymphs of T. aridifolia and H. patellifera were primarily defensive reactions, whereas the frequency of aggressive reactions tended to increase with developmental stage. S. maculata did not display aggressive reactions during any stage. I concluded that the primary and secondary defenses used by mantids depend on the developmental stage and mantid?foe distance. Moreover, three mantid species that vary in both body size and habitat showed different defensive reactions when faced with a natural enemy.

Phytoseiid mite species composition in Japanese peach orchards estimated using quantitative sequencing

David Wari[1], Shoji Sonoda[2], Yoko Kohara[3], Suqin Gerile[4]

[1]Okayama University, Japan, [2]Okayama University, Japan, [3]Okayama University, Japan, [4]Okayama University, Japan

The phytoseiid mites are regarded as potential biological control agents for spider mites. Information related to phytoseiid mite species composition is important for spider mite control. However, phytoseiid mite species identification based on morphological characteristics alone is sometimes difficult, because inter-specific differences are often subtle and the collected individuals can lack distinguishing morphological features. In this study, we established the method to estimate phytoseiid mite species composition using quantitative sequencing. Ribosomal gene fragments were amplified from genomic DNA of five phytoseiid mite species inhabiting peach orchards in Okayama Prefecture using PCR. Based on the nucleotide sequences of the amplified products, species-specific polymorphic sites were identified. Newly amplified products from recombinant plasmids were mixed in various ratios to yield standard DNA template mixtures. After direct sequencing, the signal ratios between two nucleotides at each species-specific polymorphic site were calculated and shown against the corresponding expected ratios. Quadratic regression equations were used to estimate the phytoseiid mite species composition. Results reveal that the phytoseiid mite species composition is seasonally changed and varied among study sites.

Sexual behavior, chemical communication, and reproductive isolation in *Proeulia auraria* Baker (Lepidoptera: Tortricidae)

Tomislav Curkovic[1], Yuri Cuevas[2], Luis Reyes-Garcia[3], Jan Bergmann[4], Carolina Ballesteros[5]

[1]University of Chile, Chile, [2]University of Chile, Chile, [3]Catholic University of Valparaiso, Chile, [4]Catholic University of Valparaiso, Chile, [5]University of Chile, Chile

During 2011 spring, about 1,000 Proeulia auraria larvae were collected in a vineyard and reared in the laboratory. Observations of adult females allowed determining that they perform calling behavior during the scotophase between 2 and 8 a.m., mostly after 5 a.m. The calling behavior is characterized by activation of the resting female, followed by elevation of the wings and partial exposure of the putative pheromone gland at the terminalia. Tested females performed this sequence the first three nights after emergence. Pheromone glands were excised and extracted in hexane, as well as the rest of the abdomens, at calling times. By means of gas chromatography-mass spectrometry, E11-14Ac and 14Ac were identified from glands but not from the rest of the abdomen samples. Two field trials conducted in a vineyard severely infested with P. auraria showed that males were strongly attracted to traps baited with E11-14Ac, in doses between 0.1 and 10 mg/septa*trap. However, when E11-14Ac was mixed with E11-14OH in identical concentrations (as used in commercial lures in Chile), male captures were significantly reduced. When the alcohol was used alone, captures did not differ from control traps. It is hypothesized that E11-14OH acts as an inhibitor for P. auraria males, and might be used by other synchronic and sympatric native tortricids that share similar niches (host plants), to avoid interspecific matings. We acknowledge the support to the grant FONDECYT 1110365 from the Chilean Commission for Research in Science and Technology.

Flexible food-searching in the parasitic wasp, *Cotesia vestalis*

Soichi Kugimiya[1], Masayoshi Uefune[2], Takeshi Shimoda[3], Junji Takabayashi[4]
[1]National Institute for Agro-Environmental Sciences, Japan, [2]Kyoto University, Japan, [3]National Agricultural Research Center, Japan, [4]Kyoto University, Japan

Female parasitic wasps should not only forage for hosts to increase current reproduction, but should also forage for food to increase future reproduction through their own survival. Females of the endoparasitic wasp, Cotesia vestalis, attack larvae of the diamondback moth (Plutella xylostella) to lay eggs, but they don't exploit the hosts as a food source by so-called 'host-feeding'. Under laboratory conditions, we demonstrated that female wasps could utilize non-host food sources, such as floral nectars and honeydew of a homopterous insect. Female wasps lived significantly longer on flowers of Brassica rapa than on water alone, and they also survived significantly longer when provided with plants infested with non-host green peach aphids (Myzus persicae) than when provided with uninfested plants alone. In a dual-choice test, starved female wasps showed a significant preference for a B. rapa inflorescence over an inflorescence stem with flowers removed. The same female wasps showed no significant preference between aphid-infested and uninfested plants before they experienced these plants. However, female wasps that had been previously exposed to aphid-infested plants with honeydew significantly preferred aphid-infested plants to uninfested ones. These results suggest that parasitic wasps have cognitive abilities to find a variety of potential food sources and learn to recognize cues associated with foods. This flexible foraging behavior could allow them to increase their lifetime reproductive success.

Effect of alternating temperature on life table parameters and predation capacity of phytoseiid spider mite predators

Dominiek Vangansbeke[1], Lien De Schrijver[2], Thomas Spranghers[3], Bruno Gobin[4], Luc Tirry[5], Patrick De Clercq[6]

[1]Ghent University, Belgium, [2]Ghent University, Belgium, [3]Ghent University, Belgium, [4]Proefcentrum voor Sierteelt, Belgium, [5]Ghent University, Belgium, [6]Ghent University, Belgium

Despite the large body of studies on the effect of constant temperatures on the biology of arthropods, the influence of varying temperatures remains largely understudied. In modern horticultural practice, however, considerable daily temperature variations are tolerated in the temperature integration approach. This energy saving strategy may have an influence on the development and performance of beneficial arthropods, including phytoseiid predatory mites. In the present study, life table parameters and predation rates of Phytoseiulus persimilis Athias-Henriot and Neoseiulus californicus McGregor were examined when fed with different life stages of the two-spotted spider mite Tetranychus urticae Koch at two constant temperatures (15°C and 20°C) and one alternating temperature (20°C/5° C). Rearing at the alternating temperature resulted in a significantly faster development compared to the corresponding mean temperature for both species. Combined with the higher overall reproductive performance this resulted in higher intrinsic rates of increase (rm). The rm increased from 0.086 to 0.114 for N. californicus and from 0.122 to 0.165 for P. persimilis for the alternating (20°C/5°C) and the corresponding mean temperature (15°C), respectively. When presented with T. urticae eggs, P. persimilis and N. californicus consumed more eggs at 20°C/5° C than at 15°C. However, when presented with nymphs of T. urticae no significant differences in predation rate were found between the alternating and corresponding mean temperature.

Development, survival and reproduction of *Harmonia axyridis* (Pallas) (Coleoptera: Coccinellidae) after its eggs exposure to high temperature stress

Shize Zhang[1], Zhu Cao[2], Tongxian Liu[3], Fan Zhang[4]

[1]Northwest A & F University, China, [2]Northwest A & F University, China, [3]Northwest A & F University, China, [4]Beijing Academy of Agricultural and Forestry Sciences, China

The multicolored Asian ladybeetle, Harmonia axyridis (Pallas) (Coleoptera: Coccinellidae), is a well known biocontrol agent. This study investigated the subsequently developmental, survival and reproductive traits of H. axyridis when its eggs were exposed to 25 (control), 37, 39 and 41°C for 1 hour, and then transferred to control condition. The hatching rate of eggs significantly differed among temperature treatments. The development, survival, weight, reproduction and longevity exhibited significant differences with temperature treatment and sex. The preimaginal development of females was not significant differences, while males exhibited dramatically differences with the increase of temperature. The survival rate of immature declined, while the adult fresh weight of both sexes markedly increased with the increase of temperature. Heat exposure of the eggs caused a subsequent reduction in longevity, oviposition period and reproduction, but the pre-oviposition period prolonged as the temperature increased. Interestingly, the fecundity showed increase from 37 to 39℃, though there was no significant difference; moreover, the latter oviposition period was shorter than that of the former. These may imply that the reproductive investment increased in higher level stressful environments, and the response of adult individuals could be linked to the experiences from early stages of the life history. Our findings firstly provide useful information for predicting population dynamics and distribution and also for better utilities of H. axyridis as biocontrol agent under variable environment.

Climate warming increased fitness of the cicada, *Cryptotympana facialis*, by synchronizing its hatching time with the rainy season

Minoru Moriyama[1], Hideharu Numata[2]

[1]National Institute of Advanced Industrial Science and Technology (AIST), Japan, [2]Kyoto University, Japan

Climate change can disrupt the synchrony between organisms' requirements and resource availability, leading substantial changes in population and community structures. Here we address an impact of phenological shift by climate warming on fitness of Cryptotympana facialis (Hemiptera, Cicadidae). The population of this species drastically increased in Osaka, Japan in the late 20th century, and this change has been presumed to be related to climate warming. This species has a unique trait that hatching is induced in response to rain. As frequency of rain oscillates seasonally, phenological relationship between hatching time and the rainy season is supposed to influence the hatching success of the cicada. We showed that synchrony of the rainy season and hatching time could determine hatching success, by shifting the time of completion of embryonic development and supplying water at various intervals. We estimated the change in hatching time over the last eleven decades (1901?2009) based on the meteorological records and the temperature-dependent rate of C. facialis embryogenesis. Our estimation demonstrated that warming had advanced the hatching time by about two weeks during the 20th century, and improved synchrony with the rainy season in the late 20th century. The probability of hatching success was markedly variable and often very low before this synchronization, but became stably high thereafter. Therefore, the stabilizing effect of this synchrony on fitness was indispensable to the recent population increase of C. facialis.

Macrodiplosis (Diptera: Cecidomyiidae) in Japan and Korea together with information on their ecological traits and gall induction on *Quercus* (Fagaceae)

Wanggyu Kim[1], Kiyoko Matsunaga[2], Naohisa Gyoutoku[3], Tsuneo Minami[4], Kzunori Matsuo[5], Junichi Yukawa[6]

[1]Kyushu University, Japan, [2]Chikushino, Fukuoka, Japan, [3]Kurume, Fukuoka, Japan, [4]Asahikawa, Hokkaido, Japan, [5]Kyushu University, Japan, [6]Kyushu University, Japan

Leaf-margin fold galls on Quercus mongolica (Fagaceae) has been known to occur in Hokkaido, Japan. In the spring of 2011, many leaf-margin fold galls were found on the leaves of Q. serrata in southern Japan and Korea. Larval morphological features and the structure of galls indicated that these galls were induced by species of Macrodiplosis (Diptera: Cecidomyiidae). DNA sequencing data showed that the Macrodiplosis sp. 1 on Q. serrata was different from Macrodiplosis sp. 2 on Q. mongolica and closely related to a European M. roboris that is responsible for leaf-margin fold galls on Q. robur. All known Macrodiplosis species are univoltine and larvae develop quickly into third instars and quit the galls to drop down to the ground before summer. However, it is remarkable that Macrodiplosis sp. 1 passes through spring, summer and autumn as second instar and spins cocoons in the galls in November before leaf fall. In September 2011, we found leaf-margin fold galls of sp. 1 also on Q. mongolica in central Japan. At that time, the larvae already spun cocoons in the galls. The larvae seemed to develop more quickly in northern areas than in southern areas. The larvae of sp. 1 were parasitized by an unidentified ectoparasitoid through second to third larval stadia. We are now expecting adults emerging in the early spring of 2012.

Effects of barley chromosome addition to wheat on feeding preference and nymphal development of the migratory locust *Locusta migratoria* (Orthoptera: Acrididae)

Makoto Tokuda[1], Shunji Suematsu[2], Seiji Tanaka[3], Kanako Kawaura[4], Yasunari Ogihara[5]

[1]Saga University, Japan, [2]Saga University, Japan, [3]National Institute of Agrobiological Sciences at Ohwashi, Japan, [4]Yokohama City University, Japan, [5]Yokohama City University, Japan

The migratory locust Locusta migratoria exhibits density-dependent phase polyphenism and is potentially one of the most destructive agricultural pests worldwide. The locust feeds on various Poaceae such as wheat, but does not eat barley. Identification of the barley genes inhibiting feeding by the locust is useful for developing resistant crops. Using six barley chromosome disomic addition lines of wheat (2H-7H), we investigate the effects of barley chromosome addition to wheat on feeding preference and nymphal development of L. migratoria. Feeding preference by locust hatchlings was investigated by choice tests in which wheat and one of the chromosome addition lines were presented to locust hatchlings for 24 hours. The mean amount of wheat consumed by hatchlings (control) was significantly larger than that of 2H, 5H, and 6H fed-locusts. Growth performance of the hatchlings fed with wheat, barley, or 2H-7H was assessed by examining their survival rate and developmental period. The duration of the first instar for hatchlings given 2H or barley was significantly longer than that for those given wheat or the other addition lines. Based on these results, we conclude that the barley genes involved in the inhibition of feeding by locusts are located on barley chromosomes 2, 5, and 6, and those responsible for slow development of the locust on barley chromosome 2.

Male-killing *Wolbachia* and mitochondrial selective sweep in a migratory African insect

Robert Iain Graham[1], Kenneth Wilson[2]

[1]*University of Sydney, Australia,* [2]*Lancaster University, United Kingdom*

Numerous recent studies have shown that resident symbiotic microorganisms of insects play a fundamental role in host ecology and evolution. Wolbachia pipiensis infections and the co-inherited marker, mtDNA, were examined as a method to explore the evolutionary history and population biology of the agricultural pest, African armyworm (Spodoptera exempta), a highly migratory and destructive species in sub-Saharan Africa. Three strains of Wolbachia were detected, one of which was found to be a male-killer, and genetically identical to a previously described Wolbachia from the Blue Moon Butterfly, Hypolimnas bolina. Partial sequencing of the mitochondrial COI gene from 164 individual armyworm of known infection status revealed 17 different haplotypes. There was a strong association between Wolbachia infection status and mtDNA haplotype, with only a single haplotype, haplo1 (90.2% prevalence), harbouring the endosymbiont. This indicates that Wolbachia may be driving a selective sweep on armyworm haplotype diversity. Despite very strong biological and molecular evidence (including from nuclear 28S gene markers) that the samples represent a single species (S. exempta), the 17 haplotypes did not fall into a monophyletic clade within the Spodoptera genus; with six haplotypes (2 each from 3 geographically separate populations) differing by >11% in their nucleotide sequence to the other eleven. This has clear implications for the use of mtDNA as neutral genetic markers in insects, and also demonstrates the impact of Wolbachia infections on host evolutionary genetics.

Microsatellites reveal a strong subdivision of genetic structure in Chinese populations of the mite *Tetranychus urticae* Koch (Acari: Tetranychidae)

Sun Jingtao[1], Xiao-Yue Hong[2]

[1]*Nanjing Agricultural University, China,* [2]*Nanjing Agricultural University, China*

Background: Two colour forms of the two-spotted spider mite (Tetranychus urticae Koch) coexist in China: a red (carmine) form, which is considered to be native and a green form which is considered to be invasive. The population genetic diversity and population genetic structure of this organism were unclear in China, and there is a controversy over whether they constitute distinct species. To address these issues, we genotyped a total of 1,055 individuals from 18 red populations and 7 green populations in China using eight microsatellite loci. Results: We identified 109 alleles. We found a highly significant genetic differentiation among the 25 populations (global FST=0.506) and a low genetic diversity in each population. In addition, genetic diversity of the red form mites was found to be higher than the green form. Pearson correlations between statistics of variation (AR and HE) and geographic co-ordinates (latitude and longitude) showed that the genetic diversity of the red form was correlated with latitude. Using Bayesian clustering, we divided the Chinese mite populations into five clades which were well congruent with their geographic distributions. Conclusions: Spider mites possess low levels of genetic diversity, limit gene flow between populations and significant and IBD (isolation by distance) effect. These factors in turn contribute to the strong subdivision of genetic structure. In addition, population genetic structure results don't support the separation of the two forms of spider mite into two species. The morphological differences between the two forms of mites may be a result of epigenetic effects.

Invasion genetics of the western flower thrips in China: Evidence for genetic bottleneck, hybridization and bridgehead effect

Xian-Ming Yang[1], Xiao-Yue Hong[2]

[1]Nanjing Agricultral University, China, [2]Nanjing Agricultral University, China

The western flower thrips, Frankliniella occidentalis (Pergande), is an invasive species and the most economically important pest within the insect order Thysanoptera. F. occidentalis was initially detected in Kunming in southwestern China in 2000 and since then it has rapidly invaded several other localities in China where it has greatly damaged greenhouse vegetables and ornamental crops. Controlling this invasive pest in China requires an understanding of its genetic makeup and migration patterns. Using the mitochondrial COI gene and 10 microsatellites, we investigated the genetic structure and the routes of range expansion of 14 F. occidentalis populations in China. Both the mitochondrial and microsatellite data revealed that the genetic diversity of F. occidentalis of the Chinese populations is lower than that in its native range. Two previously reported cryptic species (or ecotypes) were found in the study. The divergence in the mitochondrial COI of two Chinese cryptic species (or ecotypes) was about 3.3% but they cannot be distinguished by nuclear markers. Hybridization might produce such substantial mitochondrial-nuclear discordance. Furthermore, we found low genetic differentiation (global FST = 0.043, P < 0.001) among all the populations and strong evidence for gene flow, especially from the three southwestern populations (Baoshan, Dali and Kunming) to the other Chinese populations. The directional gene flow was further supported by the higher genetic diversity of these three southwestern populations. Thus, quarantine and management of F. occidentalis should focus on preventing it from spreading from the putative source populations to other parts of China.

Seasonal trends and physiological condition of the green stink bugs, *Nezara viridula* and *N. antennata* (Heteroptera: Pentatomidae) caught in the light trap

Nobuyuki Endo

NARO Kyushu Okinawa Agricultural Research Center, Japan

The southern green stink bug, Nezara viridula (L.) (Heteroptera: Pentatomidae) is a serious agricultural pest throughout the world. In recent years, N. viridula has been expanding its range northward in Japan, probably due to the global warming. To develop the monitoring system of N. viridula, we investigated the seasonal and temporal trends of attraction to the light trap, and also compared the attraction with its allied congener, the oriental green stink bug, Nezara antennata Scott, which is widely distributed in Japan. The sex ratio of the N. viridula adults caught in the light trap was highly female-biased, yet almost equal numbers of N. antennata adults were caught throughout the experimental period. After September, still a large number of N. viridula adults were caught in the light trap, while few number of N. antennata were caught. During the scotophase, N. viridula were caught mainly before midnight, while N. antennata were caught mostly after midnight. These results suggest that the response to the light or the flying activity during the scotophase varied between these two species. Physiological condition, especially ovarian development of females, fluctuated during the season, and the possibility of predicting the changes of seasonal history of these Nezara species is discussed.

Evolutionary convergence of leafy moth and butterfly wing patterns to establish functional modules

Takao K. Suzuki[1], Hideki Sezutsu[2]

[1]National Institute of Agrobiological Sciences, Japan, [2]National Institute of Agrobiological Sciences, Japan

Camouflage is adaptive morphological traits, resemblance to natural objects including leaves and lichens. Such mimetic patterns are typically composed of several components, and seem to achieve a specific integration to make an adaptive performance. However, how the mimetic leafy patterns are integrated has been little investigated. Here, we developed a novel method, "morphometrical network analysis", to reveal variational modules of leafy moth/butterfly wing patterns. As a model organism, we used a noctuid moth, Oraesia excavata, and a nymphalid butterfly, Kallima inachus, which closely resemble leaves with a leaf venation patterning. According to phylogenetic analysis, these two species independently evolved their leafy patterns. Our quantitative analysis indicated that in both species the constituent components of the leafy patterns are tightly coupled as modules, each of which corresponds to each component of the leaf venation pattern (i.e., the main, right-hand, and left-hand venation patterns). Interestingly, comparative morphological analysis (based on ground plan of lepidopteran wing patterns) showed that two leafy patterns are composed of the same set of homologous elements, but the correspondent leaf veneation components are established by using different elements. To put it all together, we concluded that the modules corresponding to the leaf venation components were emerged through convergence evolution, strongly suggesting that modules detected here are adaptive consequences in response to natural selection. Our results may suggest that the modules likely improve the visual trick of leafy camouflage.

Brood parasitism in two species of spider wasps (Hymenoptera: Pompilidae: Dipogon), with notes on a novel reproductive strategy

Akira Shimizu[1], Yutaka Nishimoto[2], Shun'ichi Makino[3], Katsuhiko Sayama[4], Kimiko Okabe[5], Tomoji Endo[6]

[1]Tokyo Metropolitan University, Japan, [2]Obayashi Sacred Heart Junior & Senior High School, Japan, [3]Forestry and Forest Products Research Institute, Japan, [4]Hokkaido Research Center, Forestry and Forest Products Institute, Japan, [5]Forestry and Forest Products Research Institute, Japan, [6]Kobe College, Japan

Wasps of brood parasitic species do not themselves hunt, but rather exploit prey caught by other individuals. These species either lay an egg on paralyzed prey being transported by another species (type A), or else they sneak into the nests of other species and lay their eggs on or near the stored prey (type B). Hatched larvae of the parasite then consume the usurped prey, taking the place of the host larvae. The purpose of this study was to verify the existence of type B brood parasitism in the two pompilid species, Dipogon iwatai and D. nagasei, based on nesting records. To observe nest contents, we used the trap-nest technique, which was indispensable for this study because these species are rare and their behavior is difficult to observe in the field. As a result of our observations, it was found that D. nagasei brood parasitized other species of Dipogon, whereas D. iwatai brood parasitized Auplopus carbonarius, together with several species of Dipogon. Both brood parasitic species are with the subgenus Nipponodipogon, whereas the Dipogon hosts are in the subgenus Deuteragenia. Comparison of their ecological and morphological features revealed that brood parasitism in D. nagasei is considerably more derived than in D. iwatai. Of particular note is the fact that in D. nagasei the female routinely lays up to five eggs on a single host spider, all of which develop into adult wasps without larval cannibalism; almost all Pompilidae previously studied lay only one egg on a host spider.

Maternal oviposition site selection in the stinkbug *Urostylis westwoodi* (Hemiptera: Urostylidae).

Nahomi Kaiwa[1], Takahiro Hosokawa[2], Takema Fukatsu[3]

[1]The University of Tokyo, Japan, [2]National Institute of Advanced Industrial Science and Technology (AIST), Japan, [3]National Institute of Advanced Industrial Science and Technology (AIST), Japan

In many organisms, development and success of their offspring is strongly affected by maternal oviposition strategies. Plant-sucking stinkbugs (Hemiptera: Pentatomomorpha) adopt various oviposition strategies, such as difference in clutch sizes and a variety of maternal cares. Stinkbugs of the family Urostylidae are distributed in southern and eastern Asia, with five species in Japan. All three Japanese Urostylis species lay their eggs on the trunk of Quercus trees toward the end of autumn, and after about three months, the eggs hatch in the end of winter. Of special note is that their egg masses are covered with a huge amount of jelly-like substance secreted by mother insect during oviposition. This substance is the sole food source for nymphs, on which they grow to 3rd instar toward early spring. Here we report a field survey of oviposition patterns by females of Urostylis westwoodi. Our observational data revealed that egg masses of U. westwoodi tend to be laid on the northern side of the tree trunks. The orientational differences of oviposition sites affected the sun-shade patterns, and consequently thermal patterns the egg masses experienced. Namely, in the egg masses oriented to the south, the eggs tended to hatch earlier and the nymphs tended to grow faster. These results suggest that the northward ovipositional site selection by U. westwoodi females is not for maximal nymphal growth, but is likely for avoidance of desiccation of the jelly-like substance and also for adjustment of the nymphal development to the timing of plant bud opening.

Phototactic behavior and visual function between nymphs and alates of a termite, *Zootermopsis nevadensis* (Hagen)

Wakako Ohmura[1], Motohiro Wakakuwa[2], Kentaro Arikawa[3], Masaru Hojo[4], Takuma Takanashi[5], Yutaka Kataoka[6], Makoto Kiguchi[7]

[1]Forestry and Forest Products Research Insutitute, Japan, [2]The Graduate University for Advanced Studies, Japan, [3]The Graduate University for Advanced Studies, Japan, [4]University of the Ryukyus, Japan, [5]Forestry and Forest Products Research Insutitute, Japan, [6]Forestry and Forest Products Research Insutitute, Japan, [7]Forestry and Forest Products Research Insutitute, Japan

Most castes of termites usually avoid bright light, but alates do not. The alates fly out from their nests in the daytime, and are attracted to street lights at night. In this study, we used the Dampwood termite, Zootermopsis nevadensis, which swarms during daytime, to investigate the differences in phototactic behavior between nymphs and alates. We also determined the spectral sensitivity of compound eyes based on electroretinogram (ERG) to clarify the relationship between the behavior and visual function. In behavioral assays, nymphs walked away from the light source of 350-375 nm (UV) and 400-425 nm (violet?blue). However, alates were strongly attracted to the area irradiated with the same lights, and even flied toward the light source repeatedly. Neither nymphs nor alates responded to 620-700 nm (red) light. The spectral sensitivity of nymphs had the primary peak at 520 nm (green) and the secondary peak at 360 nm (UV). In alates, we found the primary peak at 360 nm and the secondary peak at 520 nm. No sensitivity was detected in 620-700 nm neither nymphs nor alates. These results indicate that relationship between the phototactic behavior and spectral sensitivity in both nymphs and alates are strong in the UV and weak in the green wavelength region.

Overview of pheromone diversity in hawk moths based on receptor and behavioral responses

Takuya Uehara[1], Hideshi Naka[2], Shigeru Matsuyama[3], Tetsu Ando[4], Hiroshi Honda[5]

[1]University of Tsukuba, Japan, [2]Tottori University, Japan, [3]University of Tsukuba, Japan, [4]Tokyo University of Agriculture and Technology, Japan, [5]University of Tsukuba, Japan

Sphingidae is a large group in Bombicoidea with ca. 1,400 species and also a well-studied group of insects. However, the sex pheromones of this family have been identified in only a few species. We investigated the sex pheromone systems of hawk moths and found diversity in sex pheromone components. In the present study, we surveyed male responses to the sex pheromone components at both levels of odorant receptor and behavior. Insects were collected from the campuses of Tottori University and University of Tsukuba and reared under laboratory conditions. Sex pheromone components were determined by conventional methods. Pheromone candidate compounds were clarified by gas chromatography-electroantennographic detection (GC-EAD). Chemical structures of the candidate compounds were determined by GC-mass spectrometry (GC-MS) and GC analysis. In pheromone gland extracts, 10,12-hexadecadienals, 11-hexadecenals and 9,11-pentadecadienals were found to be sex pheromone candidates from 14 species of hawk moths. Behavioral responses of male moths to the sex pheromones were examined by field trap tests with synthetic lures. Male moths were exclusively attracted to the natural components of conspecific females. GC-EAD analysis was also conducted to determine the spectral ranges and sensitivities of male antennal pheromone receptors to these compounds. Diversity of sex pheromones in hawk moths will be discussed from the perspectives of peripheral receptor and behavioral responses.

Host specificity of Poropoea morimotoi and reasons for this specificity

Kazumu Kuramitsu[1], Katsuki Komizo[2]
[1]*University of Tsukuba, Japan,* [2]*Kagoshima prefectural Kokubu highschool, Japan*

Attelabid beetle females roll leaves to provide food for their brood, and some species cut off the leaf rolls. Poropoea morimotoi Hirose 1963 (Hymenoptera: Trichogrammatidae) is the most common egg parasitoid of attelabid beetles in Japan. Female wasps have a long ovipositor to lay eggs in the beetles' egg in the leaf rolls. Eleven species of attelabid beetles are recorded as hosts of P. morimotoi. However, there are no studies on host specificity in a biotic community of attelabid beetle species. In this study, we examined the parasitic status of P. morimotoi in 2 biotic communities that include 6 species of beetles throughout a year. We demonstrated that P. morimotoi can successfully parasitize certain species of the beetles. In addition, our results suggested two reasons for this host specificity. One is the length of the ovipositor of the wasps makes it so they can lay eggs only on species in small leaf rolls and cannot lay eggs on species in large leaf rolls. Second is the influence of beetle behavior. Wasps mainly parasitized suspended leaf rolls so cutting off a leaf roll may be a barrier for wasps to lay eggs. In conclusion, wasp host specificity may be determined by differences in leaf roll size and leaf roll cutting behavior of attelabid beetles.

Strepsipteran parasites (Strepsiptera: Stylopidae) control their host's pollination behavior.

Yuta Nakase[1], Makoto Kato[2]

[1]Kyoto University, Japan, [2]Kyoto University, Japan

Strepsiptera, known as 'twisted-winged parasites', is an insect order with nine families making up about 600 species. They are parasites of other insects. The male is the winged, dispersal stage; females are apterous, larviform, and viviparous and permanently reside within their host in all but the most basal family. The sclerotized head end (cephalotheca) of larviform females typically protrudes slightly from between host tergites, copulating with a male and exiting many small first instar larvae through a brood-canal opening on the cephalothorax. Usually parasitized hosts lose their fecundity. First instar larvae of Stylopidae strepsipterans show specialized forms for phoresy. The larvae disperse by phoresy through flowers to reach and parasitize eggs and larvae of host bees. Parasitized host bees lose their fecundity and nest building instincts. Though bees visit flowers and collect pollen and nectar, they feed only nectar. Adult bees collect pollen as food for larvae, so parasitized bees that don't build their nests need not collect pollen. When the parasitized bees visit flowers that provide only pollen as reward, the bees gain nothing by visiting flowers. While it is efficient for strepsipterans to infest new host by they control parasitized bees to flowers where nests building non-stylopized bees visit frequently. In this study, we observed the pollination behavior of stylopized bees and revealed that strepsipteran parasites control the pollination behavior of their host bees.

Does host plant regrowth mediate coexistence of herbivorous insects?

Koya Hashimoto[1], Takayuki Ohgushi[2]
[1]Kyoto University, Japan, [2]Kyoto University, Japan

The Competitive Exclusion Principle predicts that two species sharing a same niche cannot coexist. However, many specialist herbivorous insects coexist despite of sharing their host plant in the field. There is increasing evidence that interspecific interactions among herbivorous insects are mainly mediated by food plant responses. Such indirect interaction may mediate coexistence of herbivorous insects. However, information about long-term outcomes (i.e. coexistence or exclusion) of such indirect interactions is still lacking. In 2011, we studied an exotic butterfly Sericinus montela and a native butterfly Atrophaneura alcinous sharing the same host plant Aristolochia debilis. Only these butterflies can feed on A. debilis, and they have no specific natural enemies due to defensive chemicals sequestered from A. debilis in their body tissue. In the field, leaves of A. deibilis were often consumed completely by these caterpillars, but they can regrow after some time and then were eaten again by other caterpillars. These results suggested that these two butterflies are coexisting not because their resources are abundant, and that such plant regrowth may mitigate the competitive interaction between the two butterfly species. We will show whether the plant regrowth promotes coexistence of the two butterfly species.

Recovery of aquatic insects in a pond of Fukushima, Japan after The Great North Eastern Japan Earthquake & Tsunami

Toshimasa Mitamura[1], Shigeyuki Yoshii[2], Kei Hirasawa[3]

[1]Fukushima Agricultural Technology Centre, Japan, [2]Fukushima Entomological Society, Japan, [3]Aquamarine Fukushima, Japan

The Great North Eastern Japan Earthquake & tsunami on March 11TH, 2011, inundated the coastlines of Fukushima prefecture. This force damaged many human lives and biodiversity. In addition to this, the habitat of the organisms was exposed to radiation from the accident at the Fukushima No. 1 nuclear power plant. Therefore investigation of natural environment is not progressing in the coastlines of the Fukushima Prefecture. We investigated a pond near the coastline of Fukushima Prefecture. This fresh water pond (about 260 m2 , about 60 cm deep) was in the damaged area of tsunami, Matsukawaura, Soma city. Twenty-three days after the tsunami, the salinity of this pond was 1.25% (April 3, 2011), and it decreased to 0.08% after a year of tsunami (March 19, 2012). Aquatic insects of 20 species (4 order 8 family) were found in this pond from 2008 to 2010. Aquatic insects were very few in numbers after the tsunami. Then the number of insects increased gradually, and aquatic insects of 25 species (4 order 8 family) were found in one year. The number of larva of Aeschnidae decreased. On the other hand, 10 species (Coleoptera: 6 species, Hemiptera: 4 species) were newly recorded. Out of the 10 species, 3 species, Cymatia apparens, Anisops ogasawarensis, Eretes sticticus, are especially high in numbers. The insect fauna of this pond changed dramatically after the tsunami.

Overwintering strategy of the egg parasitoid wasp *Trissolcus plautiae*: Enhanced cold tolerance and reduced reproductive ability in response to photoperiod

Masatoshi Toyama[1], Koji Mishiro[2], Fumio Ihara[3], Morio Higaki[4]

[1]NARO Institute of Fruit Tree Science, Japan, [2]NARO Institute of Fruit Tree Science, Japan, [3]NARO Institute of Fruit Tree Science, Japan, [4]NARO Institute of Fruit Tree Science, Japan

The egg parasitoid wasp Trissolcus plautiae (Watanabe) (Hymenoptera: Scelionidae) is the most important natural enemy of Plautia stali Scott (Hemiptera: Pentatomidae), a serious pest causing fruit damage in Japan. Females of this wasp overwinter maintaining their reproductive activity without being induced into reproductive diapause. The wasp's overwintering ability depends on the emergence date. Observations under natural conditions in the Kanto region Japan showed a sharply reduced survival after November for females that ended development before mid-August, whereas not for females that emerged after mid-August. The light regime experienced in the larval stage has a remarkable effect on the cold tolerance of adults. Females reared under a long photoperiod of 16L:8D had a low survival rate at -5 ºC or below, and survived less than one month even at 5 ºC, whereas those reared under a short light period of 10L:14D maintained a high survival rate over two weeks at -7.5 ºC. Although experimental combinations of temperature and photoperiod during development did not lead females to reproductive diapause, the number of eggs in ovaries was significantly reduced by a short photoperiod. Science its host has a large variation in seasonal occurrence, this overwintering strategy of improved cold tolerance and holding fewer matured eggs is likely an adaptation to the unpredictable availability of resources in time and space.

Pupae of a rhinoceros beetle produce deceptive vibratory signals to protect themselves against conspecific larvae

Wataru Kojima[1], Yukio Ishikawa[2], Takuma Takanashi[3]

[1]University of Tokyo, Japan, [2]University of Tokyo, Japan, [3]Forestry and Forest Products Research Institute, Japan

It is argued that animal signals may have evolved so as to manipulate the response of receivers in a way that increases the fitness of the signallers. In deceptive communication, receivers incur costs by responding to the false signals. The larvae of Japanese rhinoceros beetle Trypoxylus dichotoma (Coleoptera, Scarabidae, Dynastinae) construct their own pupal cells to ensure normal pupation and eclosion. These cells are fragile and subject to damage from burrowing larvae because this species shows a highly aggregated distribution in the field. Recently, we reported that pupae of this species produce vibratory signals to deter conspecific larvae, thereby protecting themselves (Kojima et al. 2012 Behav Ecol Sociobiol). In the present study, monitoring of vibrations associated with larval movement revealed that T. dichotoma larvae remained motionless (freeze response) for ca. 10 min when pupal vibratory signals were played back transiently. Furthermore, pupal signals of T. dichotoma elicited a freeze response in three other scarabaeid species from Cetoniinae and Rutelinae, whose pupae do not produce vibratory signals. This indicates that the freeze response to certain types of vibration evolved before the divergence of these species, and has been evolutionarily conserved presumably because of the fitness advantage in avoiding predators. Pupae of T. dichotoma have probably exploited preexisting anti-predator responses of conspecific larvae to protect themselves by emitting deceptive vibratory signals.

Community-wide impacts of foliar herbivory on flower visitors

Mito Ikemoto[1], Shunsuke Utsumi[2], Takayuki Ohgushi[3]
[1]Kyoto university, Japan, [2]University of Tokyo, Japan, [3]Kyoto university, Japan

It has been accepted that foliar herbivory has an indirect and negative impacts on plant reproductive success by reducing pollinator visitation. However, indirect effects of early-season foliar herbivory on floral visitation of non-pollinators such as florivores and predators, which may also influence pollinator visitation, are poorly appreciated. To fully understand the effects of foliar herbivory on plant reproductive success, we need to explore its impacts on overall community structure of flower visitors including non-pollinators. In this study, we examined how foliar herbivory can influence community structure of floral visitors. To address this question, we conducted an inoculation experiment using lace bug (Corythucha marmorata), which is a predominant herbivorous insect attacking Solidago altissima in Japan. In damaged plants, plant height, flower numbers and branches with flowers significantly decreased compared to undamaged plants. Also, flowering phenology was significantly delayed in damaged plants. Relative pollinator abundance except for flies did not differ between damaged and undamaged plants. The number of non-pollinators, including spiders, stink bugs, caterpillars, and grasshoppers decreased on damaged plants. The pollinator visitation was positively correlated with flower number. However, non-pollinator visitation was not related to the flower number, suggesting that changes in the floral quality may affect non-pollinators visitation. We found that overall community structure of flower visitors significantly differed between damaged and undamaged plants.

Genetic evaluation of the bumblebee (Hymenoptera, Apidae), *Bombus deurteronymus maruhanabachi*, endangered species of semi-natural grasslands in Nagano, Japan

Hiroyuki Tanaka[1], Takeshi Suka[2], Atsushi Ushimaru[3], Takakazu Yumoto[4]

[1]Kyoto University, Japan, [2]Nagano Environmental Conservation Research Institute, Japan, [3]Kobe University, Japan, [4]Kyoto University, Japan

The bumblebee Bombus deuteonymus deuteronyms (Bdd) adapts to grasslands in East Asia, including Hokkaido, Japan. The subspecies B. d. maruhanabachi (Bdm) is endemic to Honshu island of Japan and shows close connection to semi-natural grasslands, which is a type of grassland that has been maintained by human activities. This grassland is considered one of the refugia for many plant and insect species that had immigrated to Japan from Asian continent probably through Korean Peninsula. Rapid decline of semi-natural grasslands during the 20th century in Japan is deeply concerned to reduction and fragmentation of habitats for grassland species. The present study aims to characterize genetic diversity of Bdm distributed in Nagano Prefecture, Japan by comparing with Bdd populations from Primorsky Territory, Russia and Hokkaido, and also two other species of Bombus (B. hypnorum and B. hypocrita) living in Nagano. Ten loci of microsatellite DNA were genotyped and population genetic parameters were calculated. Based on comparison of allelic richness and mean heterozygosity, genetic diversity of the Nagano population of Bdm was lower than the Primorsky population of Bdd, and also lower than two other Bombus species. The results of AMOVA showed no genetic structure in Bdm, but pairwise population differentiation analysis revealed significant differentiation between some local populations in Nagano. Mean population relatedness was higher in Bdm population comparing to two other species in Nagano. These results suggest a sign of degradation of habitat environments for Bdm and other grassland species.

Oviposition behavior of rice leaf bug *Trigonotylus caelestialium* (Kirkaldy) and sorghum plant bug *Stenotus rubrovittatus* (Matsumura)

Atsuhiko Nagasawa
Tohoku University, Japan

The rice leaf bug Trigonotylus caelestialium and sorghum plant bug Stenotus rubrovittatus are important pests of rice plants in Japan. These insects cause formation of discolored grains known as pecky rice. Further, the main hosts of these insects are Poaceae plants. Here, I investigated suitable plant species for studying the oviposition behavior of these mirid bugs. Adult mirid bugs oviposited on various Poaceae and Cyperaceae. Nymphs of T. caelestialium emerged from both spikelets and leaf sheaths, whereas those of S. rubrovittatus emerged almost exclusively from the spikelets. Eggs of T. caelestialium were also observed on both spikelets and leaf sheaths, whereas those of S. rubrovittatus were observed only on the spikelets of some plants. These indicate that the preference of oviposition sites is different between T. caelestialium and S. rubrovittatus. To understand the difference between preference of oviposition sites of T. caelestialium and S. rubrovittatus, I observed the following oviposition behavior of these mirid bugs: The adult mirid bugs always inserted their stylets into the spikelets before oviposition. After pulling the stylet out of the spikelet, the adult inserts its ovipositor into the same place. This behavior indicates that the adult bug recognizes the oviposition site using its stylet. I observed T. caelestialium show such searching behavior on leaf sheaths using its stylet, whereas no such behavior was shown by S. rubrovittatus. Thus, these 2 bugs might recognize oviposition sites before using their stylets.

Ability of making trench determines host plant range of cucurbit feeding insects

Makoto Abe[1], Koji Noge[2], Shigeru Tamogami[3]

[1]Akita Prefecutural University, Japan, [2]Akita Prefecutural University, Japan, [3]Akita Prefecutural University, Japan

Cucurbit feeding insects, such as Aulacophora and Epilachna beetles, make trench on their cucurbit host plant leaves before feeding on it, protecting the feeding site from sap exudation. Although these insect species have different host plant range each, they feed on non-host cucurbit plants when provide the detached leaves from the whole plant body. In laboratory experiments using whole plant body and the detached leaves of pumpkin and Trichosanthes plants, Epilachna admirabilis (hereafter Ea, host plant: Trichosanthes) fed on the detached leaves of pumpkin, a non-host plant, without making trench; however, Ea did not make a trench on the whole body leaves of pumpkin, nor they fed on it. Aulacophora indica (hereafter Ae, host plant: pumpkin and Trichosanthes etc.) fed on both whole body and the detached leaves of Trichosanthes as well as pumpkin. Observation by a stereoscopic microscope revealed that bite marks and sap exudation remained on surface of the leaves of whole pumpkin body by Ea. This suggests that capability of trench makes the host plant range: Ae has high ability of making trench to prevent sap from exuding and Ea do not make a trench effectively to prevent sap from exuding from whole pumpkin plants. Further feeding mechanisms and factors influencing the host plant selection by Ae, Ea and other cucurbit feeding insects will be discussed.

Fatty acid-amino acid conjugates diversification in Lepidopteran caterpillars

Naoko Yoshinaga[1], Sayo Morita[2], Ritsuo Nishida[3], Naoki Mori[4]
[1]Kyoto University, Japan, [2]Kyoto University, Japan, [3]Kyoto University, Japan, [4]Kyoto University, Japan

Fatty acid amino acid conjugates (FACs) have been found in noctuid as well as sphingid caterpillar oral secretions; in particular, volicitin [N-(17-hydroxylinolenoyl)-L-glutamine] and its biochemical precursor, N-linolenoyl-L-glutamine, are known elicitors of induced volatile emissions in corn plants. These induced volatiles, in turn, attract natural enemies of the caterpillars. In a previous study, we showed that N-linolenoyl-L-glutamine in larval Spodoptera litura plays an important role in nitrogen assimilation which might be an explanation for caterpillars synthesizing FACs despite an increased risk of attracting natural enemies. However, the presence of FACs in lepidopteran species outside these families of agricultural interest is not well known. We conducted FAC screening of 29 lepidopteran species, and found them in 19 of these species. Thus, FACs are commonly synthesized through a broad range of lepidopteran caterpillars. Since all FAC-containing species had N-linolenoyl-L-glutamine and/or N-linoleoyl-L-glutamine in common, and the evolutionarily earliest species among them had only these two FACs, these glutamine conjugates might be the evolutionarily older FACs. Furthermore, some species had glutamic acid conjugates, and some had hydroxylated FACs. Comparing the diversity of FACs with lepidopteran phylogeny indicates that glutamic acid conjugates can be synthesized by relatively primitive species, while hydroxylation of fatty acids is limited mostly to larger and more developed macrolepidopteran species.

Measuring trunk volatiles of spruce (*Picea abies*) using an optimized trunk enclosure

Christine Rachow[1], Martin Gabriel[2], Stefan Schutz[3]

[1]University Gottingen, Germany, [2]University Gottingen, Germany, [3]University Gottingen, Germany

Volatiles (Volatile Organic Compounds, VOCs) play an important role in host plant finding and host plant choice of insects. In contrast to volatiles released by leaves, the release of volatiles from tree trunks and their impact on xylophagous insects is not well known yet. Trunk volatiles are expected to be of significant importance in the host finding process of wood living insects. This study presents an improved method for the sampling of trunk volatiles with reduced cost and time expenditure. The method is based on a flexible PET enclosure and a volatile trapping unit. The flexible PET foil is used to constitute an isolated space around a cylindrical part of the trunk. The volatiles released by the trunk are constantly extracted for two hours in an open loop mode. The samples are trapped on Tenax traps and CLSA-traps. These samples are desorbed by a Thermal Desorption System (TDS) and by chemo-desorption, respectively. The chemical analysis is performed by a gas chromatograph with a mass spectrometric detector (GC-MS).

Genetic structure of *Planococcus ficus* (Hemiptera: Pseudococidae) from vineyards in Egypt.

Margarita Correa[1], Elie Poulin[2], Shaaban Abd-Rabou[3], Hassan Shalaby[4], Thibaut Malausa[5]

[1]Facultad de Agronomia e Ingenieria Forestal, Pontificia Universidad Catolica de Chile, Chile, [2]Departamento de Ciencias Ecologicas, Facultad de Ciencias, Universidad de Chile, Chile, [3]Plant Protection Research Institute, Dokki, Gaza, Egypt, [4]Plant Protection Research Institute, Dokki, Gaza, Egypt, [5]UMR ISA (INRA,UNSA,CNRS). 400 route des Chappes. 06903 Sophia-Antipolis, France

Planococcus ficus is an important pest in vineyards worldwide. Despite its economic importance, the taxonomic status of its populations is still unclear. For example, populations from Egypt and Israel currently referred to as P. ficus were formerly split into two species then synonymized by Cox & Ben-Dov in 1986. Recent DNA barcoding results in Egypt revealed substantial genetic variations among samples at several DNA markers, hence calling for further investigations of the population genetic structure. In this work, we investigated the genetic structure of P. ficus populations in Egyptian vineyards. Populations from 5 regions were collected and subjected to DNA sequencing at the mitochondrial gene Cytochrome oxidase I. The population genetic diversity and genetic structure were studied by estimating standard diversity and Fst indices, and performing an analysis of molecular variance. Fifteen COI haplotypes were observed. Significant genetic differentiation was detected among populations with Fst ranging from 0.471 to 1. Among regions genetic differentiation was moderate with Fst values from 0.076 to 0.349. The Mantel test showed no significant correlation between genetic and geographical distances. Our results do not provide evidence of the occurrence of more than one taxon. Rather, the observed high genetic diversity suggests that Egypt is part of the native region of one species. The results also suggest that the population genetic structure is mainly driven by genetic drift. This is likely the consequence of repeated demographic bottlenecks caused by pesticide treatments; each population probably corresponds to the progeny of few surviving individuals from the previous generation.

Behavioral response of *Harmonia axyridis* towards their footprints according to their physiological state

Delphine Durieux[1], Berenice Fassotte[2], Georges Lognay[3], Frederic Francis[4], Eric Haubruge[5], Francois J Verheggen[6]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium, [6]University of Liege - Gembloux Agro-Bio Tech, Belgium

In order to survive cold, the multicolored Asian ladybeetle, Harmonia axyridis (Pallas), aggregates inside dwellings during winter. It has been recently highlighted that overwintering H. axyridis individuals lay an area marking while walking, which is used by conspecifics to locate aggregation sites. These footprints are made-up of hydrocarbons, comprising both saturated and unsaturated homologues. However, it has not been demonstrated whether this "following area marking" behavior is specific to the overwintering individuals. The work presented herein was oriented to the study of the chemical evolution of these footprints according to the physiological state of H. axyridis. Monthly GC-MS analyses revealed that the area marking contained a greater amount of di-unsaturated compounds when laid by overwintering ladybeetles, suggesting the great importance of these chemicals in the ladybeetles aggregation process. In the second instance, behavioral investigations conducted in a Y-shaped glass tube were performed to assess (1) the evolution of H. axyridis behavior towards their footprints and (2) whether this behavioral modification is due to an evolution of the ladybeetles sensitivity or rather to an evolution of the area marking attractiveness. The results revealed that only the overwintering individuals follow their area marking, and that this behavior is linked to the ladybeetle physiological state rather than to the chemical profile of the marking biomolecules.

Characterization of *Harmonia axyridis* (Pallas) overwintering sites

Berenice Fassotte[1], Delphine Durieux[2], Frederic Francis[3], Eric Haubruge[4], Francois J Verheggen[5]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium

Originally introduced as a biological control agent, the multicoloured Asian ladybeetle, Harmonia axyridis (Pallas), has become an invasive pest throughout Europe and North America in the last few years. Although its effectiveness to control aphid and coccid populations was impressive, some negative impacts appeared rapidly, notably on human health. Indeed, to protect themselves from cold temperatures, H. axyridis individuals move inside dwellings and buildings and form large aggregations in concealed portions of structures to overwinter. The aggregating beetles are responsible for some annoyances due to, on one hand, the number of individuals inside homes and, on the other hand, the hemolymph secretions they release when they are disturbed, which can cause allergic reactions. In order to highlight the specific features of infested houses, we investigated a large number of overwintering sites in Wallonia between 2007 and 2011. These sites were characterized through a survey sent to homeowners confronted to invasion problems. This survey was mainly focused on a general description of the infested house (type, colour, infested floor(s), building material), the orientation of the colonized rooms and the position of the beetles' cluster. The collected data indicate that H. axyridis preferentially selects isolated brick houses with red or white fronts to take shelter. Aggregations are mostly located at the first floor, essentially inside south or west oriented rooms. Furthermore, ladybeetles generally gathered into wooden windows frames facing south or west, and to a lesser extent, in the upper corners of walls presenting the same orientation. All these results

The effects of organic and conventional management strategies on biodiversity and ecosystem functioning in paddy fields

Dina Wahyu Trisnawati[1], Takayuki Tsukamoto[2], Satoru Sato[3], Hironori Yasuda[4]

[1]UGAS, Iwate University, Japan, [2]Yamagata University, Japan, [3]Yamagata University, Japan, [4]Yamagata University, Japan

Recently, conventional farming has caused serious ecological problems such as loss of biodiversity, although organic farming may be beneficial for conserving biodiversity and improving the agroecosystem. There are several studies suggesting that biodiversity in organic was higher than conventional farming, however, it still remains unclear how these management ways influence on the ecosystem processes. We expected that different nutrient in the soil between the two management ways might influence the ecosystem processes and affect biodiversity. Field researches were conducted to understand the biodiversity in organic and conventional farming. In general, biodiversity between organic and conventional farming was not significantly different. In addition, to understand ecosystem processes, experiments regarding feeding behaviour of the most abundance herbivore such as grasshopper were conducted in a laboratory. Feeding preference and performance of the grasshopper increased when rice plants in conventional farming were fed as food, because soil nutrient such as Nitrogen in the conventional farming was higher than organic farming. These results suggested that the method of management would influence on soil nutrient and give different impacts on biodiversity in a paddy field.

Electrophysiological and behavioural responses of *Thanatophilus sinuatus* Fabricius (Coleoptera: Silphidae) to selected cadaveric odors

Jessica Dekeirsschieter[1], Christine Frederickx[2], Frederic Francis[3], Georges Lognay[4], Yves Brostaux[5], Eric Haubruge[6], Francois Verheggen[7]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium, [6]University of Liege - Gembloux Agro-Bio Tech, Belgium, [7]University of Liege - Gembloux Agro-Bio Tech, Belgium

The sense of smell or olfaction is crucial for insects and carrion insects are not exception to this, they have adapted their olfactory system over millions of years to specific cadaveric chemicals. Forensic entomologists often raise the hypothesis that these cadaveric compounds regulate the necrophagous insect's behavior and are responsible to the attraction of carrion insects to the corpses, including Silphidae. Nevertheless, it is not known which chemical cues are involved in the attractiveness of the carcass. So far, little information is available on the chemical ecology of carrion beetles, particularly concerning the subfamily of Silphinae. Silphinae are frequently found on vertebrate carcasses and may be present in great numbers. Thanatophilus sinuatus F. is frequently found in Europe on vertebrate carcasses. The biological role of selected cadaveric volatile organic compounds including: dimethyldisulfide (DMDS), butan-1-ol, n-butanoic acid, indole, phenol, p-cresol, putrescine, and cadaverine on the silphine species, Thanatophilus sinuatus, was investigated by using both electrophysiological and behavioural techniques. Among the tested cadaveric compounds, butan-1-ol and DMDS elicited the strongest EAG from both T. sinuatus male and female antennae. In a two-arm olfactometer, males and females were significantly attracted to dimethyldisulfide (DMDS) for both tested doses, whereas only males were attracted to p-cresol at 100 ng. Putrescine was repellent to males at the dose of 1 µg.

Volatile organic compounds released by barley roots attract wireworms

Fanny Barsics[1], M Fiers[2], Frederic Francis[3], Eric Haubruge[4], Francois Verheggen[5]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium

Wireworms are the soil dwelling larvae of click beetles and are pests of many crops worldwide. Alternatives to insecticide treatments are needed in order to develop integrated management strategies. Our work consists in elucidating the role of barley root-emitted volatile organic compounds on the orientation behaviour of Agriotes sordidus wireworms. Using a dual choice olfactometer we have evaluated the attractiveness of a variety of baits ranging from barley roots themselves to isolated root-emitted volatile organic compounds. Wireworms were significantly attracted towards most of the tested baits. Our results should be taken into account in varietal selection, in crop rotation, or in trapping systems aiming at the reduction of the populations of this pest.

AQUATIC INSECTS IN ALPINE LAKES (SLOVAKIA, EUROPE): A SMALL-SCALE POPULATION-GENETIC STUDY

Zuzana Ciamporova-Zatovicova[1], Fedor Ciampor[2]

[1]Institute of Zoology Slovak Academy of Sciences, Slovakia, [2]Institute of Zoology Slovak Academy of Sciences, Slovakia

High mountain lakes of glacial origin belong to the most remote and undisturbed aquatic environments over the world, and their recovery from anthropogenic pollution, or reactions to climate change are hot topics of freshwater research. Population genetic studies of alpine lakes inhabitants mostly describe genetic patterns in large scale (between mountain ranges). However, we still know very little about population structure of alpine aquatic insects within smaller areas. In the High Tatra Mountains, there are more than 110 permanent lakes of glacial origin and many small ponds. In 2009, we promoted the study of genetic variability of aquatic insects of these biotopes starting with beetles Agabus bipustulatus and Agabus guttatus (Coleoptera: Dytiscidae). For haplotype analysis we used 350bp fragment of cytochrome b mtDNA. Among ca 450 samples, relatively small haplotype diversity was detected, with different distribution in both species. Most of lakes was characterized by single haplotype and majority of haplotypes were restricted to only one of sampled valleys. Consequently, the detailed analysis of microsatellites of both specie will follow. Results of analysis based on molecular methods can contribute considerably to the knowledge on the distributional trends, recolonization or identifying refugia of the species. Consequently they can help to preserve these unique aquatic environments and their biodiversity. Beside population study, the data on intraspecific variability will serve for development of determination technology of animal species using DNA. This contribution/publication is the result of project implementation (ITMS: 26240220049) supported by the R&D OP funded by the ERDF.

Is the univoltine papilionid, *Luehdorfia japonica* (Lepidoptera), declining by the climatic warming?

Minoru Ishii[1], Tetsuo Tanikawa[2]

[1]*Osaka Prefecture University, Japan,* [2]*Osaka Prefecture University, Japan*

The univoltine papilionid butterfly, Luehdorfia japonica (Lepidoptera), is endemic to the Honsyu Island in Japan. Adults appeared in and around 'Satoyama' coppices in spring, and larvae, which feed on leaves of Asarum herbs (Aristolochiaceae), pupate in early summer. The pupae successively undergo two kinds of diapause, summer and winter diapause terminated by autumnal short day and winter cold, respectively (Ishii and Hidaka, 1983). This species is ranked as an endangered species in Japan, but the extinction rate of population is higher in regions with warmer winters than those with colder ones (Ishii, 2010; Tanikawa and Ishii, 2010), suggesting that the recent climatic warming threatens this species. In this study, we reared eggs, larvae and pupae in the state of winter diapause under various temperature conditions in order to clarify the influence of hotter summer and warmer winter on the survival rate. As for the eggs and larvae, all individuals died at 30C, while about 90% of individuals survived at temperatures between 15 and 25C. Pupae were subjected to 9 temperature and photoperiodic conditions (Experiments 1-9) after the termination of summer diapause by a 2-month exposure to 20C-12L-12D. Adult emergence was observed in 6 experiments where pupae were subjected to 0 or 10C for 4 months before a transfer to 20C-16L-8D. In contrast pupae exposed to 20C-12L-12D for more than 2 months died at the pharate adult stage. The results demonstrate that this species is not able to survive summers as hot as 30C and winter as warm as 20C.

A trophic cascade effect of *Toxorhynchites rutilus* (Diptera: Culicidae) predation on aquatic bacteria

Daniel Simoes Albeny[1], Evaldo Ferreira Vilela[2], Steve A. Juliano[3]

[1]Federal University of Vicosa, Brazil, [2]Federal University of Vicosa, Brazil, [3]Illinois State University - Normal, IL, U.S.A.

Feeding by container-dwelling mosquito larvae may negatively affect microorganism richness or abundance. However, indirect effects of predators of mosquitoes on microorganisms are poorly studied. Larvae of the predator Toxorhynchites rutilus prey on larval Aedes triseriatus, which feed on bacteria. We postulated that a trophic-cascade arises from T. rutilus predation on A. triseriatus larvae, impacting bacterial abundance within water-filled containers. Experimental microcosms (450ml plastic cups holding 300ml of deionized water) received 100ml of oak leaf infusion (35mg/L, 9 days old) as a bacterial source and 100 first-instar A. triseriatus larvae. Treatments were: prey alone; prey with one T. rutilus larva; and prey with water-borne predatory cues, which consisted of water that had held one T. rutilus larva feeding on A. triseriatus larvae for 5 days. Controls were: infusion alone; or infusion plus predatory cues. We measured bacterial production via 3H leucine incorporation every 7 days14 days. As predicted, bacterial abundance was greater in the predator treatment than in others. Bacterial abundance did not differ between predator and predatory cues treatments. We hypothesized that predator and predatory cues treatments contain partially eaten prey, increasing bacteria abundance. We tested this in an experiment in which A. triseriatus were either crushed, crushed and removed, or subject to real predation. Controls received 100 first instar A. triseriatus larvae. Surprisingly, bacterial abundance was greater with real predation than in all other treatments. We suggest that feces (from either predator or prey) or reduced foraging induced by predator cues contributed to bacterial growth.

Considering associate plant diversity to enhance biological control of *Dacryodes edulis* (G Don) in Gabon

Rene Noel Poligui[1], Mouaragadja Isaac[2], Eric Haubruge[3], Frederic Francis[4]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]Institut des Superieur d'Agronomie et de Biotechnologies(INSAB), Universite des Sciences et Techniqu, Gabon, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium

The monitoring of entomofauna among associated plants integrating Dacryodes edulis was carried out in Gabon in 2009 and 2010, using yellow traps and visual control. Two kinds of home gardens were described from the rural and urban areas where the studies occurred. Fifty one plant species were identified, with 47% of fruit trees, 23% of food crop plants and 29% of wild plants. Dacryodes edulis was the major (21%) of fruit trees in these home gardens. Our results showed that in home gardens dominated by fruit trees, the insect's abundance provided by yellow traps were higher (14897 insects) than in the home gardens with mixed fruit trees and herbaceous crops (13031 insects). Visual control allowed to record closely balanced abundance of insects, with 4901 insects on Dacryodes edulis from home gardens dominated by fruit trees, and 5188 insects on D. edulis of associate plant gardens. However, Shannon Index calculation shows no variation of insect's diversity recorded in both home gardens. The major pest caught by traps belong to Aphididae (20,2%), Cicadellidae(6,1%) and Psyllidae (22,8%), while those of visual control were Cecidomyiidae(8,9%), Crambidae(8,4%), and Stictococcidae (4,1%). In regards to these results, exploiting associated plants around D.edulis could avoid insect outspread and damage on this fruit tree. Further studies are to make in this way in order to enhance biological control of D.edulis in Gabon

Insects associated with *Jatropha curcas* in the Brazilian Cerrado

Talita Gomes Pereira[1], Jorio Saraiva Furtado de Mendonca[2], Charles Martins de Oliveira[3], Alexei de Campos Dianese[4], Marina Regina Frizzas[5]

[1]Universidade de Brasilia, Brazil, [2]Embrapa Cerrados, Brazil, [3]Embrapa Cerrados, Brazil, [4]Embrapa Cerrados, Brazil, [5]Universidade de Brasilia, Brazil

Jatropha curcas L. (Euphorbiaceae) is an important alternative source for biodiesel production in Brazil and worldwide. Despite their hardiness, jatropha plants are often attacked by pests and diseases that can lead to severe losses. This study surveyed the insects associated with jatropha in the brazilian cerrados, and was conducted in an area of 1.3 ha, located at Embrapa Cerrados, Planaltina/DF (15 ° 35 '42.7' S, 47 ° 44 '14.8' W, 1039 m), with 3 to 4 year-old plants. Samples were collected biweekly for 6 months, between November/2011 and April/2012. Insects were collected on 10 randomly selected plants in the area, taking in account all above-ground plant parts. They were identified as to their functional group (chewing/sucking feeding habits, predators, parasitoids, detritivores and pollinators), order, family and morphospecies. In total, 905 insects were collected in 9 orders, 40 families and 109 species. The order Hemiptera was the most abundant (76%). Most of the insects were collected on the leaves. Individuals from all functional groups were collected, with emphasis on sucking insects (73%) and predators (15%). Pachycoris torridus (Scopoli) (Hemiptera: Scutelleridae) was the most abundant species (54%). The months with the highest number of insects collected were February (29%), March (26%) and January (22%). Knowledge of the main pests and their natural enemies brings key information for management strategies in this culture, as the area planted with jatropha increases in an impressive rate in Brazil.

The nocturnal egg parasitoid *Paratelenomus saccharalis*

Keiji Takasu
Kyushu University, Japan

Although host foraging behavior of many parasitoids has been intensively studied in the laboratory, it is unknown for most of the parasitoid what time of the day they are active in the field. In the present study, I discovered that the egg parasitoid Paratelenomus saccharalis are active from dusk to dawn. The host Megacopta punctatissima laid egg masses consisting of 10-40 eggs on buds and stems of the kudzu from 1100 to 1300. Paratelenomus saccharalis females appeared on or near host egg masses from 1600 to 1900. No female appeared on the host egg masses from 800 to 1500. Soon after arriving at host eggs, females rested near host egg masses without ovipositing. From dusk into night, they were parasitizing. It took 5-12h for a female to complete ovipositing in an average of 17 eggs before leaving a host. When a female parasitized a host egg mass, she left the hosts before 2400. However, when a female approached a host egg mass where another female had been parasitizing, the ovipositing female showed aggressive behavior toward the invading female. After finding another female, the resident spent more time patrolling and less time ovipositing. The invader attempted to sneak in to the host egg mass for oviposition unless she found another unoccupied egg mass nearby. When two females were on the same host egg mass, they remained the host egg mass and continued the war of attrition type competition for more than 12 hours or until next morning.

Advantage of sex in aphids: A case study using *Acyrthosiphon pisum*

Shin-ichi Akimoto[1], Takashi Kanbe[2]
[1]*Graduate School of Agriculture, Hokkaido University, Japan,* [2]*Graduate School of Agriculture, Hokkaido University, Japan*

A number of hypotheses have been proposed to explain the advantages of sexual reproduction over asexual reproduction. However, few attempts to test the hypotheses have been conducted because of difficulty establishing a good biological system. In the present study, we tried to test the advantage of sex over asexual reproduction by using aphids, for which we can experimentally switch sexual to asexual reproduction and vice versa. In northern Japan, the pea aphid, Acyrthosiphon pisum is obligatorily sexual in the wild, with the sexual generation in autumn. However, if the aphid is reared in the laboratory in a long photoperiod, they can continue to reproduce asexually. We had maintained 2 originally sexual clones asexually for 5 years before the experiments. Muller's ratchet hypothesis would expect the accumulation of deleterious mutations during the long period of enforced asexual reproduction. We successfully induced the sexual generation for the 2 clones by placing them in a short photoperiod, and crossed them to obtain fertilized eggs. We compared fitness components (viability and fecundity) between the offspring clones and the 2 parental clones at the same time. We observed many examples of genetically unfit offspring, i.e. failure of development in hatched larvae (fundatrices) and sterility of some adult fundatrices. As a result, our experiments indicated that all the offspring clones that once established had higher expected fecundity than did the parental clones. This result suggests that sexual reproduction led to appearance of healthy and fecund offspring by producing many unfit offspring, i.e. by purging deleterious mutations.

The flighty ability of the diamondback moth *Plutella xylostella* (Lepidoptera: Plutellidae) tested using flight mill

Bao-Cai Shi[1], Shu-Jun Wei[2], Ya-Jun Gong[3]

[1]Beijing Academy of Agriculture and Forestry Sciences, China, [2]Beijing Academy of Agriculture and Forestry Sciences, China, [3]Beijing Academy of Agriculture and Forestry Sciences, China

The study of its flight ability is essential to understanding the pattern of migration. Here, the flight ability of 1, 3, 5 and 7 day aged moths and the mated and unmated moths are tested using flight mill in laboratory. The results show that female moths of different age have different flight ability. The moths emerged after one-day show the worst flight ability, while those emerged after 3 days show the best flight ability, with a longest flight distance of 10.546 Km and flight duration of 11.613 h within 12 successive hours. The male moths emerged after 1, 3, 5 and 7 days show no difference with a longest flight distance of 13.191 Km and flight duration of 12.000 h. The mated and unmated male and female moths do not show difference in flight ability. After flight, the longevity and fecundity of the moth are reduced. However, the mated and unmated moths do not show different in longevity and fecundity after flight.

Annual fluctuation and food habits of *Hydrometra procera*

Ryo Funato[1], Kouhei Murata[2]

[1]Tokai University, Japan, [2]Tokai University, Japan

Hydrometra procera is one of the semi-aquatic bugs found in paddy fields. I investigated the population fluctuation and food habits of the species to evaluate its potential as a biological control agent against Sogatella furcifera, Nilaparvata lugens, and Nephotettix cincticeps in a paddy field under sustainable cultivation. Through the present study, arthropods belonging to the following 7 taxa were sucked by the bug ;Onychiuridae gen. sp., S.furcifera, N.lugens, N.cincticeps, Chironomidae gen. sp., Brachycera gen. sp. And Theridiidae gen. sp. Population density of the bug in the paddy field showed two peaks a year, in late June and in September. The former peak tended to synchronize with a peak of S.furcifera nymphs , while the latter peak with N.lugens, N.cincticeps, and collembolans. Therefore, main food resource of the bug should be these insects in the paddy field. Ovarian development of the bug under field condition revealed that the bug could be uninvoltine since females possessing mature ovary appeared once a year, from June to Jurly. Rearing tests in laboratory at 22, 27 and 31℃ showed a developmental zero(T?) of 14.0℃ with a thermal constant(K) of 250℃-day from egg to adult for the bug, H. procera.

Predation,development and oviposition of *Hydrometra procera* (Heteroptera:Hydrometridae) under laboratory conditions

Naoki Takeda[1], Kouhei Murata[2]

[1]Tokai University, Japan, [2]Tokai University, Japan

Hydrometra procera is one of semiaquatic bugs in the paddy fields. We investigated the fecundity and predatory characteristics of this bug to evaluate the potential 23℃,25℃,30℃ and 35℃ under a 16L-8D photoperiod. The functional response of H. procera to prey density was saturation curve, and the maximum number of prey killed was 1.65 per day against WBPH dropped on the water surface. The averages of the total number of eggs laid per female were 10.5, 20.8,19.5 and 7.5 at 35℃,30℃,25℃ and 23℃, respectively. The total number of eggs laid were 100.8,186.2,223.2 and 64.1 at 23℃,25℃, 30℃ and 35℃, respectively. Survival rate of immature stages at 25℃ was significantly higher than at 23℃,30℃ and 35℃. The average of egg period were 5.9 days, 7.4 days and 8.7 days at 30℃,25℃ and 23℃,respectively. Egg period significantly decreased with increasing temperature. The five nymphal instars require 13.1 days at 25℃ to reach aduls . The development period of nymphs significantly decreased with increasing temperature.

Quantitative genetics of the Desert Locust's larval growth: Rate and life-history strategy

Benjamin Pelissie[1], Marie-Pierre Chapuis[2], Christine Pages[3], Cyril Piou[4]

[1]CIRAD, France, [2]CIRAD, France, [3]CIRAD, France, [4]CIRAD, France

Schistocerca gregaria, the desert locust, which is distributed from north-west Africa to south-east Asia, is one of the most known and studied locust species. In order to prevent local human populations from the threat of pullulations, we need to know more about population dynamics of the desert locust, especially for the solitarious populations which are less studied than gregarious ones. Predicting the evolution of population dynamics needs a good knowledge of life-history traits that influence population demography. Growth is one of these traits, since it is directly linked to the onset of sexual maturity, then reproduction. Moreover, in order to investigate the potential of selection on individual growth, one needs to evaluate its heritability by disentangling genetic and additive variation in traits phenotype from non-genetic variance due to other (environmental) factors. Here we present a work done on a first generation lab population of S. gregaria sampled in the field. We recorded individual larval growth of 15 full-sib families, based on body weight and morphology in controlled conditions. We describe larval growth by analyzing growth rate as well as several key variables involved in life-history strategy (body weight and size at emergence, growth rate until adult emergence, maximum body weight, age at adult emergence, larval strategy). Thanks to the known relatedness structure of our sample, we also calculate the heritability of those traits and make predictions about the ability of S. gregaria populations to respond to selection on larval growth.

Spatio-temporal dynamics of baculovirus infections in a major African crop pest, *Spodoptera exempta*

Kenneth Wilson[1], Robert Iain Graham[2], Wilfred Ludovik Mushobozi[3], David Grzywacz[4]

[1]Lancaster University, United Kingdom, [2]Lancaster University, United Kingdom, [3]EcoAgriConsult Ltd., Tanzania, [4]University of Greenwich, United Kingdom

African armyworm (Spodoptera exempta) is a major pest of cereals (maize, wheat, sorghum, rice) and pasture grasses in sub-Saharan Africa, especially in eastern Africa, where it is a major pest in 9 out of every 10 years. S. exempta is subject to a specific baculovirus infection, S.exempta nucleopolyhedrovirus (SpexNPV), which is being developed as a microbial pesticide for use in Tanzania. Here, we report on a 4-season study exploring the spatial and temporal dynamics of SpexNPV in natural African armyworm outbreak populations in Tanzania using PCR and qPCR to quantify both prevalnce and intensity of virus infections. We show that baculovirus levels increase through the season and vary in relation to both co-infection levels and population density in surprising ways.

Effects of latitude and type of surrounding agricultural land on abundance of the indigenous mirid bug *Pilophorus typicus*, a generalist predator of vegetable pests

Shun-ichiro Iwase[1], Kengo Nakahira[2], Masami Takagi[3]

[1]Kyushu University, Japan, [2]Kyushu University, Japan, [3]Kyushu University, Japan

Introduction: The abundance of natural enemies on different types of agricultural lands can be affected by differences of latitude and the surrounding vegetation. Moreover, natural enemies in the surrounding vegetation can immigrate into agricultural lands as suppression factors of crop pest populations. Here, we report that effects of latitude and surrounding land use on the abundance of a generalist predator, Pilophorus typicus, on Kyushu Island in Japan. Materials and methods: Densities of P. typicus in 49 kudzu communities (31.25-33.19 °N) within 18 areas were determined in the summer and autumn of 2010. The following area rates of the surrounding agricultural lands were calculated in 11 spatial scales (95-3,000 m radiuses) with a vegetation map: 1) paddy-field, and 2) field, except paddy-field. Relationships of P. typicus density were analyzed with these field rates and latitudes of the kudzu communities. Results: P. typicus were collected in 29 kudzu communities (59.2 %, 31.25-33.15 °N). Densities of P. typicus decreased with increases in latitude of researched kudzu communities and the rate of surrounding paddy fields, and increased with an increase in the rate of surrounding fields, except paddy-fields. Conclusion: Conservation biological control programs using P. typicus in southern Kyushu are likely to be more effective than in northern Kyushu because of the abundance and immigration rate from kudzu communities. The results of the relationship between the abundance and agricultural lands can be used as references to evaluate the possible high immigration rate of P. typicus.

Spatial distribution and theoretic sampling sizes of oranges infested by *Bactrocera minax* in orchard

ZhiMo Zhao
Southwest University, China

The percentage of damaged fruit is a major parameter to estimate the extent of infestation caused by B. minax, and in certain degree, the spatial distribution of damaged fruits in orchard can reflect the oviposition action of B. minax. These data are the basis to establish an effective sampling technique. In this study, we investigated 118 citrus trees in an orchard in Jiang You, Sichuan province, China. Forty fruits were randomly investigated per tree, and the number of damaged fruits was recorded. The analysis of spatial distribution showed that the distribution of damaged fruits among different trees were aggregated distribution, which could be described as Neyman's distribution or Negative binomial distribution probability model. On the same tree, the damaged fruits randomly distributed, which could be described by Poisson probability model. According to the analysis of variance, the distribution of damaged fruits among different trees was significantly different (F = 1.7751, P = 0.000031), and no significant difference was detected in the distribution of the damaged fruits on the same tree (F = 0.4134, P = 0.7435). Based on the investigate data, taking the primary unit (tree) and second unit (fruit) into account, the best sample size was calculated using second order sampling model. The results indicate that in an

Genetically modified poplar as biofuel: Another opportunity for insect exploitation?

Michael Scott Crossley[1], Christine Buhl[2], Richard Lindroth[3]

[1]University of Wisconsin-Madison, U.S.A., [2]University of Wisconsin-Madison, U.S.A., [3]University of Wisconsin-Madison, U.S.A.

Global energy demands have elevated biofuel research to an unprecedented level of prominence in the last decade. The plant cell wall itself poses perhaps the most significant barrier to the feasibility of biofuel technology. Genetic modification of biofuel crops to alter cell wall composition has proven to be a promising next step toward efficient conversion of cellulose to ethanol. But an important question arises that requires investigation by entomologists: Will insects over-exploit genetically modified biofuel crops? The purpose of this study was to investigate the effects of lignin modification in poplar on leaf chemistry and consequent insect resistance and insect herbivore prevalence. Leaf samples from several modified poplar genotypes were chemically analyzed and assessed for damage by insect herbivores. Surveys were conducted to determine prevalence of insect herbivores and their natural enemies. No significant differences were found in leaf chemistry, insect resistance or prevalence, suggesting genetically modified biofuel poplar for altered lignin composition may in fact maintain resistance to insect herbivores.

Structure determination of the elicitors in the *Sogatella furcifera*(HORVATH) which make japonica rice plant (Oryza sativa L.) varieties induce ovicidal substance against the egg of *S. furcifera*

Jeong-Oh Yang[1], Naoya Nakayama[2], Chul-Sa Kim[3]

[1]Kochi University, Japan, [2]Kochi University, Japan, [3]Kochi University, Japan

Some japonica rice plant (Oryza sativa L.) varieties showed a resistance that is characterized by formation of watery lesions and production of ovicidal active compound, benzyl benzoate (B.B.) when the whitebacked planthopper lays eggs in the varieties. This B.B. results in a high mortality to eggs of S. furcifera and reduces to egg hatchability. We, therefore, have tried to elucidate mechanism for this resistant and to isolate and identify the elicitor(s) in S. furcifera. B.B was produced with the formation of watery lesions, only when 80% MeOH extract (20females of S. furcifera equivalent) was applied on to the surface of the rice plant (ver. Natsuhikari) after the plant was hurt by the sewing needless. This result clearly shows that the elicitor(s) in the S. furcifera makes japonica rice plant induce ovicidal substance against the egg of S. furcifera. The elicitor(s) were eluted in the 100% MeOH and 100% EtOH fractions (frs) on a reversed phased ODS open column. The both frs induced B.B. at 43.95 μg/g of fresh rice plant (frp) and 31.04 μg/g frp, respectively. The further separation of the active 100% MeOH fr by using a reverse phased HPLC column leads to isolate five active compounds and the structures of each compound were determined by using NMR, LC-MS and GC-MS spectra as 1, 2-dilinoleoyl phosphatidyethanolamine (22.4 μg/ 20 females), 1, 2-dipalmitoyl-sn-glycero-3-phosphoethanolamine(3.32 μg/ 20 females), 1-palmitoyl-2-oleoyl-X-glycero-3-phosphoethanolamine (7.96 μg/ 20 females) and 1, 2-dioleoyl-sn-glycero-3-phosphoethanolamine (5.12 μg/ 20 females), respectively.

Keywords:*Sogatella furcifera, benzyl benzoate, 1, 2-dilinoleoyl phosphatidycholine, 1, 2-dilinoleoyl phosphatidyethanolamine, 1, 2-dipalmitoyl-sn-glycero-3-phosphoethanolamine, 1-palmitoyl-2-oleoyl-X-glycero-3-phosphoethanolamine, 1, 2-dioleoyl-sn-glycero-3-phosphoethanolamine, ovicidal compound, elicitor,*

Comparison of life-history traits of two cryptic species in *Brontispa longissima* (Gestro) (Coleoptera: Chrysomelidae)

Shun-ichiro Takano[1], Keiji Takasu[2], Mika Murata[3], Nguyen Thi Huong[4], Satoshi Nakamura[5]

[1]Kyushu University, Japan, [2]Kyushu University, Japan, [3]Japan International Research Center for Agricultural Sciences, Japan, [4]Japan International Research Center for Agricultural Sciences, Japan, [5]Japan International Research Center for Agricultural Sciences, Japan

Brontispa longissima is a serious pest of the coconut Cocos nucifera supposedly originated from Papua New Guinea and Indonesia. It has recently invaded into Southeast and East Asia and its outbreaks have been reported in there. Our mitochondrial DNA analysis revealed that there are two cryptic species in B. longissima: one is distributed over a wide area including Asia and the Pacific region (herein referred to as the Asian clade) and the other in a limited area in the Pacific region (herein referred to as the Pacific clade). The distribution of Asian clade coincided with the area of recent invasions and outbreaks of this species, suggesting that only the Asian clade has become a serious invasive pest. To determine whether the Asian clade is more invasive than the Pacific clade, we compared life-history traits of the two clades on C. nucifera. Insects of the Asian clade showed larger net reproduction rates (R0), intrinsic rates of natural increase (r), and mean length of a generation (T) than Pacific clade (R0: 130.0 and 94.0, r: 0.084 and 0.083, and T: 57.7 and 54.7 in the Asian and the Pacific clade, respectively). Even there was small difference in r (0.001), the simulated population growth indicated that the number of the insects of the Asian clade would be twice and three times as many as that of the Pacific clade after five and ten generations, respectively. Rapid population growth was considered to be a factor of wide distribution and outbreaks of the Asian clade.

Does seasonal change of chemicals in the primary host plant, *H. syriacus*, stimulate the host shift by the cotton aphid (*Aphis gossypii*) from the primary host plant to the secondary host plant?

Yu Yamamoto[1], Yohei Kawasaki[2], Kana Siraki[3], Chul-Sa Kim[4]

[1]Kochi University, Japan, [2]Kochi university, Japan, [3]Kochi University, Japan, [4]Kochi university, Japan

The cotton aphid (Aphis gossypii) is a polyphagous serious pest in the world and gives many vegetables and crops damage. This species has a complex life cycle. In early spring, the cotton aphid hatched on a primary host plant, Hibiscus syriacus, has spent on it through three or four generations and then shifts the secondary host plant, for example, cucumber, egg plant and so on in early summer. In autumn, the male and female re-come back to H. syriacus and the female lays egg on it after mating. Why must the cotton aphid shift the host plant? Why cannot the cotton aphid live on the primary host plant through four seasons? We try to elucidate the reason in the view of the seasonal change of quality and quantity of chemicals in primary host plant, H. syriacus. As a result, we found that concentration of uridine became to be the maximum before a few days at the time of maximal nymph's population and that concentration of fumaric acid increased along with increase in number of alatae. When several combinations of the chemicals in the leaves of H. syriacus were artificially given to the cotton aphid through palafilm membrane with an artificial diet, the combination including fumaric acid with the maximum concentration tended to stimulate appearance of alata in next generation.

Keywords:*cotton aphid, uridine, fumaric acid, alata*

V-ATPase is involved in silkworm defense response against *Bombyx mori* nucleopolyhedrovirus

Peng Lu[1], Hengchuan Xia[2], Keping Chen[3]

[1]Jiangsu University, China, [2]Jiangsu University, China, [3]Jiangsu University, China

Silkworms are usually susceptible to the infection of Bombyx mori (B. mori) nucleopolyhedrovirus (BmNPV), which can cause significant economic loss. However, some silkworm strains are identified to be highly resistant to BmNPV. To explore the silkworm genes involved in this resistance, in present study we performed comparative real-time PCR, ATPase assay, over-expression and sub-cellular localization experiments. We found that when inoculated with BmNPV both the expression and activity of V-ATPase were significantly up-regulated in the midgut column cells (not the goblet cells) of BmNPV-resistant strains (NB and BC8), the main sites for the first step of BmNPV invasion, but not in those of a BmNPV-susceptible strain 306. Furthermore, this up-regulation mainly took place during the first 24 hours post inoculation (hpi), the essential period required for establishment of virus infection, and then was down-regulated to normal levels. Amazingly, transient over-expression of V-ATPase c subunit in BmNPV-infected silkworm cells could significantly inhibit BmNPV proliferation. To our knowledge this is the first report demonstrating clearly that V-ATPase is indeed involved in the defense response against BmNPV. Our data further suggests that prompt and potent regulation of V-ATPase may be essential for execution of this response, which may enable fast acidification of endosomes and/or lysosomes to render them competent for degradation of invading viruses.

Descriptions and comparison of antennal morphology and sensilla ultrastructure of three *Tomicus* species (Coleoptera: Curculionidae, Scolytinae)

Zhen Zhang[1], Pingyan Wang[2], Xiangbo Kong[3], Hongbin Wang[4], Sufang Zhang[5]

[1]Chinese Acedemy of Forest, China, [2]Chinese Acedemy of Forest, China, [3]Chinese Acedemy of Forest, China, [4]Chinese Acedemy of Forest, China, [5]Chinese Acedemy of Forest, China

The antennal morphology and sensilla ultrastructure of Tomicus yunnanensis, T. minor, and T. brevipilosus were studied by scanning (SEM) and transmission electron microscopy (TEM). The three species had similar morphology and sensilla type, but sensilla on antennal club segments 2, 3, and 4 in T. minor were much sparser than in T. yunnanensis or T. brevipilosus. Eight sensilla types were recorded: sensilla trichodea types 1 and 2 were located apically and on the lateral surface of the club and were innervated by five and eight dendrites, respectively; sensilla chaetica types 1 and 2 had no dendrites in the sensilla lymph lumen; sensilla basiconica, top-protuberated sensilla basiconica, and fluted cones occurred primarily on the club; and Bohm bristles occurred on scape segment 1. Sensilla basiconica were the most abundant and were innervated by 10-14 dendritic branches. Top-protuberated sensilla basiconica and fluted cones were innervated by one and five dendrites, respectively. The potential functions of these sensilla are discussed with respect to morphology and ultrastructure. We compared the sizes and numbers of each sensilla type between sexes, within species, and between two development phases. There were no statistical differences between sexes. The lengths and numbers of sensilla basiconica and sensilla trichodea type 2 differed significantly among the three species.

Predicting the risk of extinction for moths and butterflies by using shared ecological features of species and its larval food plants

Jan Sipos[1], Tomas Kuras[2], Mariana Pavlatova[3]

[1]Faculty of Science, Palacky University, Czech Republic, [2]Palacky University, Czech Republic, [3]Faculty of Science, Palacky University, Czech Republic

Recent studies predict that endangered species of butterflies are characterized by narrow niche breadth, poor ability to colonize suitable habitats and short flight period. Majority of works are focusing on butterflies and testing the effect of ecological features of species on their extinction risk. We are convinced that the inconsistent results of previous works are caused by neglecting ecological characteristics of their larval food plants. Butterflies and geometrid moths of the Czech and Slovak Republics (Central Europe) were chosen as a studied group of herbivores. Index of population distribution (proportion of occupied faunal squares among old and new records) was used as dependent variable for butterflies, whereas conservation status was used for geometrid moths. Effect of ecological characteristics of species and larval food plants were fitted by using the method of generalized least squares (GLS). Our analysis predicts that threatened butterflies and geometrid moths are characterized as thermophilous and heliophilous species preferring steppe habitats, with Mediterranean type of distribution. The best fitted characteristics of larval food plants for predicting the degree of extinction risk were (i) plant species frequency and period of a host plant flowering for the moths; (ii) Raunkiaer plant life-forms, species frequency in grid maps and nitrogen preference of plants for butterflies. Ecological characteristics of the moths explain 14% of the total variability, however, 4% of the variability are explained by characteristics of food plants. On the other hand, ecological features of the butterflies explain 54% of variability and 16% are explained by characteristics of food plants.

The influence of severe drought on the resistance of *Pinus yunnanensis* to a bark-beetle-associated fungus

Zhen Zhang[1], Xingrong Gao[2], Xudong Zhou[3], Francois Lieutier[4], Hongbin Wang[5], Xiangbo Kong[6]

[1]Chinese Acedemy of Forest, China, [2]Chinese Acedemy of Forest, China, [3]Chinese Acedemy of Forest, China, [4]Chinese Acedemy of Forest, China, [5]Chinese Acedemy of Forest, China, [6]Chinese Acedemy of Forest, China

Researches on tree response to pest attacks under drought and heat stress are crucial for predicting effect of future climate change on forest pests and tree health. We studied the influence of severe water stress on the resistance of Pinus yunnanensis to inoculation with Leptographium yunnanense, a pathogenic fungus associated with the aggressive bark beetle, Tomicus yunnanensis. Experiments were carried out during May to September 2010 and March to April in 2012 in two plots located at the top and at the foot of a hill in Xiaojiu, China. Following isolated and mass fungal inoculations, we observed the reaction zone length, fungal growth in the phloem, and the occlusion, blue-staining of the sapwood. Measurements of soil and needle water contents and predawn needle water potentials confirmed severe drought was occurred during the experiment time, especially at hilltop. Measures of fungal infection of phloem and sapwood in June were more serious than normal year. Reaction zone length and fungal extension negatively correlated with ψ. The results suggest that severe water stress under high temperature has a negative impact to tree resistance to fungal pathogens associated with Tomicus yunnanensis.

Various groups of invertebrates ? various responses for the proposal of "biodiversity-friendly management" of submontane meadows. Is there any rational compromise?

Monika Mazalova[1], Tomas Kuras[2]
[1]*Faculty of Science, Palacky University, Czech Republic,* [2]*Faculty of Science, Palacky University, Czech Republic*

The aim of this study was to evaluate impact of agricultural management and the landscape structure on insects of semi-natural grasslands. The investigated sites were flower-rich Arrhenatherion meadows with variable schemes of mowing in the submontane region of the Hruby Jesenik Mts. (Czech Republic). Insects were sampled using Moericke´s yellow traps. The response from selected groups of insects (mostly nectarivorous and phytophagous species) of changing vegetation characteristics and the landscape structure had been investigated during two vegetation seasons (2009-2010). Data were analysed using multivariate ordination technics (CCA, GLM), intensity of mowing, number of flowering plants, distance from grass balks and forest edges being independent variables. According to the results of analyses, each group of insects responses particularly different on the changing environmental conditions reflecting the agricultural measure. Nevertheless, the main role played factors of seasonality and the position of both interaction components (i.e. grass balks, forest edges). Contrary to other recent studies, immediate impact of the mowing was detectable up to the particular species (e.g. Hesperia comma, Lasiommata maera) or taxa (Bombus spp.), but not in the whole community level. On the base of this study, we can summarize: (i) the majority of insects´ abundance is localized near the margins of meadows, (ii) the highest abundances of invertebrates were collected in the main vegetation season (June, July). Therefore, (iii) the most destructive management measure in the long-term scale is the extensive mowing in the main season, covering the edge parts of the meadows.

Use of climate-based model for better understanding spatial distribution of Encyrtidae (Hymenoptera: Chalcidoidea) in North-Western Asia

George Japoshvili[1], Levan Mumladze[2]

[1]*Agrarian University of Georgia, Georgia,* [2]*Ilia State University, Georgia*

Successful use of Encyrtids as pest biocontrol agents is one of the important challenges today. In spite of this, available data of the ecology and distribution of Encyrtids are rather scarce and imperfect. There is no data to what environmental factors limit or promote (if any) the distribution of the Encyrtid species. In the present study, we collect all available distributional data for Encyrtid species from Iran, Turkey and Transcaucasian countries. Based on the collected data we produce climate based species distribution models and extrapolate them to whole northern temperate zones. Based on the received results, we have identified most species reach regions within the study area (a); for each species we have predicted the suitable habitats for potential use in future introduction (b). Our results suggest that additional investigations are needed to assess the faunal diversity in the studied region.

Life history of *Spodoptera litura* Fabricius (Lepidoptera: Noctuidae) on three cotton *Gossypium hirsutum* L. varieties

Yong Jung Kwon[1], Md Ruhul Amin[2], Dil Afrose Tithi[3], David Goulson[4]

[1]Kyungpook National University, Republic of Korea, [2]Hajee Mohammad Danesh Sci. & Technology University, Dinajpur, Bangladesh, [3]Hajee Mohammad Danesh Science and Technology University, Dinajpur, Bangladesh, [4]School of Biological and Environmental Sciences, University of Stirling, Stirling, United Kingdom

Cotton armyworm Spodoptera litura when reared on CB9, CB10 and SR05 cotton varieties showed that preoviposition and incubation periods of the moths did not differ significantly but fecundity and hatching rate were significantly different. The highest fecundity (1656.8 ± 270.6) and hatching rate (76.3 ± 16.2%) were found when the moths were provided with SR05 and CB10, respectively. Cotton varieties had significant effects on larval, prepupal and pupal periods. The highest larval (33.4 ± 2.7 day), prepupal (3.8 ± 0.4 day) and pupal (17.4 ± 1.3 day) periods were observed on CB10, CB9 and CB9, respectively. The highest pupation (92.0 ± 10.9%) and adult eclosion (81.0 ± 10.8%) rate were found on CB10 and SR05, respectively. The mating behaviour of the moths differed according to cotton variety; the longest mating duration (123.5 ± 15.3 minute) was found on SR05, compared to CB9 (102.6 ± 15.0 minute) and CB10 (113.3 ± 21.0 minute). The moths showed significantly higher mating success when they were reared on CB10. Cotton varieties did not show significant effect on the remating success of males and females. The longevity of adults varied significantly and the highest longevity of male (10.5 ± 0.9 day) and female (8.9 ± 0.8 day) moths were found when they were fed SR05. Overall, S. litura fitness appears to be highest on cotton variety SR05, suggesting that this variety is least suitable of those tested here for use in areas where S. litura is a major pest.

A climatic variables-based prediction on the distribution of an alien invasive hornet *Vespa velutina nigrithorax* in Korean Peninsula

Moon Bo Choi[1], Tae Geun Kim[2], Jong Cheol Jeong[3], Jong Wook Lee[4]

[1]Yeungnam University, Republic of Korea, [2]Korea National Park Service, Republic of Korea, [3]Korea National Park Service, Republic of Korea, [4]Yeungnam University, Republic of Korea

Vespa velutina nigrithorax is a hornet that inhabits subtropics such as southern China, Indonesia and Taiwan. Meantime, this alien invasive hornet was detected in Busan city, Korea in 2003. Furthermore, this species has been increasing continuously in the Korean Peninsula, especially in its southland that has been being a subtropical region with climatic changes. In 2011 it was found that this species spread to Daegu city to the north and to Jiri Mountain to the west, and in Busan city and the surrounding area it has been dominant over other Vespa species. Hereat, a prediction was made about the spread and distribution of the species by the application of 19 climatic variables to the maximum entropy algorithm, whereof results were analyzed by use of the Maxent species distribution prediction program. In result, this species was predicted to spread throughout the nation after proceeding southwestward and then northward. In particular, the southland is predicted to meet optimal climatic conditions for the inhabitation of this species within 2050 and the whole territory, excluding some parts of Gangwon Province and Gyeonggi Province, is predicted to do so within 2080. Their spread, of course, will exceed the foregoing climatological prediction, but it will take them the estimated time to be completely naturalized or dominant. The data, derived from this study, are expected to bestead the preparation of countermeasures for ecological disturbance, economic impacts and public health problems.

Damage type of glasswort by *Scrobipalpa salinella* (Zeller) (Lepidoptera: Gelechiidae) and Occurrence by Region

Chae Hoon Paik[1], Geon Hwi Lee[2], Jin Young Park[3], Chang Yeol Yang[4], Man Young Choi[5], Sang Soo Kim[6], Kyung Bo Lee[7]

[1]National Institute of Crop Science, RDA, Republic of Korea, [2]National Institute of Crop Science, RDA, Republic of Korea, [3]Shinan Agricultural Technology Service Center, Shinan, Jeollanam-do, Republic of Korea, [4]National Institute of Horticultural and Herbal Science, RDA, Korea, Republic of Korea, [5]National Institute of Crop Science, RDA, Republic of Korea, [6]Suncheon National University, Suncheon, Jeollanam-do, Republic of Korea, [7]National Institute of Crop Science, RDA, Republic of Korea

Damages of Scrobipalpa salinella by farming management types were divided by three types on glasswort. Type 1 is that growers not clean up debris in the farming period. Type 2 is that growers left dried glasswort not harvested in the previous year. Type 3 is that grower left the field mixed with around weed. Occurrence of Scrobipalpa salinella (Zeller) was investigated on glasswort in Shinan and Suncheon, Jeonnam and Kimjae, Jeonbuk in 2011. The occurrence of S. salinella observed from four times (in Shinan and Kimjae) to five times (in Suncheon) in a year. Adult stage of S. salinella in Shinan areas (Jeungdo, Imja island) occurred from mid-April to late September. The peak times of 1st, 2nd, 3rd and 4th generation adults of S. salinella were observed on early May, mid-June, early August and early September, respectively. In Kimjae area, the peak times of 1st, 2nd, 3rd and 4th generation adults of S. salinella were observed on early May, mid-June, late July and mid-September, respectively. In Suncheon area, the peak times of 1st, 2nd, 3rd, 4th and 5th generation adults of S. salinella were observed on early May, mid-June, early August, early September and early October, respectively.

Keywords:*Glasswort, Scrobipalpa salinella, Damage, Density, Occurrence*

Damage analysis and control method of *Laodelphax striatellus* (Fallen) (Homoptera: Delphacidae) on rice

Geon Hwi Lee[1], Chae Hoon Paik[2], Man Young Choi[3], Tae Hwan Noh[4], Hyeong Kwon Shim[5]

[1]National Institute of Crop Science, RDA, Republic of Korea, [2]National Institute of Crop Science, RDA, Republic of Korea, [3]National Institute of Crop Science, RDA, Republic of Korea, [4]National Institute of Crop Science, RDA, Republic of Korea, [5]National Institute of Crop Science, RDA, Republic of Korea

This study was carried out to know the damage aspects of rice and to develop control method of small brown planthopper (Laodelphax striatellus). The damage aspects of rice by L. striatellus at different population densities (1, 2, 3, 4/plant at seedling, 10, 20, 30, 40/plant at tillering stage) and different growth stages (seedling, tillering) were studied in rice field. The yield loss was more higher seedling stage than tillering stage of rice. The economic threshold level of L. striatellus which caused 50% loss of yield were estimated to be approximately 2 for the seedling stage and 12 for the tillering stage per plant, respectively. In the experiment, the linear relationships between density and decrease of yield were as following; seedling stage and tillering stage was Y= 4.0097X-1.6874 (R2=0.9272) and Y= 0.5281X-1.2034 (R2=0.9852), respectively. The days of control effect which caused over 80% were estimated to be approximately 20 days for seed box treatment and 40 days in seed-dressing plot of Imidacloprid compared with that of untreated plot, respectively.

Introduction of *Tanysphyrus* (Tanysphyroides) major Roelofs (Coleoptera: Curculionidae), a possible candidate agent for the biological control of *Monochoria vaginalis* var. plantaginea (Roxb.) Solms in

Jinyoung Park[1], Jong Kyun Park[2]

[1]*Kyungpook National University, Republic of Korea,* [2]*Kyungpook National University, Republic of Korea*

Monochoria vaginalis var. plantaginea (Pontederiaceae) is one of the most problematic weed in the rice field in Korea. Tanysphyrus (Tanysphyroides) major was selected as a potential biological control agent for M. vaginalis var. plantaginea. This species has a single generation per year, over-wintering as an adult stage. The emergence of adults starts in later June and last until September. Host specificity test showed that finally selected this species was suitable candidates for the biological control of M. vaginalis var. plantaginea since it showed negative host specificity against major 60 test crops. Also, the thirtythree plants of the M. vaginalis var. plantaginea were planted for the T. (T.) major releasing experiment. Every experimental plots planted with M. vaginalis var. plantaginea were treated with the adults of regulated 35, 50 and 100 pairs. Control effect to M. vaginalis var. plantaginea by the adults density of T. (T.) major were investigates. When the 25, 50 and 100 adult pairs treated in the middle stages of M. vaginalis, required period for effective biological control were 7, 6 and 4 weeks, respectively. Also, M. vaginalis var. plantaginea injured by the T. (T.) major were not regrowth and fruits. T. (T.) major adults when input 25 and 50 pairs, necessary time were required 14 weeks for biological control of later stages M. vaginalis var. plantaginea, and seed investigated number of 13,231 and 10,157, respectively. And case of 100 pairs was 11 weeks, and seed investigated number of 4,469. Seed weight was 1.63, 1.24 and 0.48g, respectively.

Genetic diversity of the long-horn beetle, *Callipogon relictus* (Coleoptera: Cerambycidae) in North Korean and Chinese populations

Tae Joong Yoon[1], Dae Am Yi[2], Won Young Choi[3], Jong Eun Lee[4]

[1]Korea University, Republic of Korea, [2]Yeongwol Insectarium, Republic of Korea, [3]National Institute of Biological Resources, Republic of Korea, [4]Andong National University, Republic of Korea

The long-horn beetle, Callipogon relictus Semenov, is distributed in Northeast Asia including South and North Korea, China, and Russia, but the populations have drastically decreased for last a few decades because of habitat destruction. So this species was listed as an "endangered wildlife species" in South Korea as in other countries. In order to establish a conservation strategy and select introduced populations, a preliminary investigation on the genetic diversity of North Korean and Chinese populations was performed using mitochondrial Cytochrome c oxidase I (COI) (470bp) and COII (718bp). A total of 17 individuals of C. relictus was collected from 3 locations in North Korea (2 locations) and China (1 location) and analyzed with respect to variability within and differentiation among populations. Partial COI and COII gene of C. relictus showed low genetic variation (COI:0.0017?0.0146, COII:0.0024-0.0039) within and differentiation (COI:0.0046-0.0124, COII:0.0026-0.0038) among populations, respectively.

The Influence of mine leachate on community structure of benthic macroinvertebrates

O Chang Kwon[1], Jong Eun Lee[2]

[1]Andong National University, Republic of Korea, [2]Andong National University, Republic of Korea

This study was conducted for determining the influence of the mine leachate on the community structure of benthic macroinvertebrates from Uiseong Okdong Mine, which located in Uiseong-gun. On August 30, 2011 an examination was made of the benthic macroinvertebrates and water quality from three sites on the experimental water system by the mine leachate from Uiseong Okdong Mine and those from 2 sites on the control water system located near the experimental water system. The identified species and individuals number were 9 species belonged to 8 families, 6 orders, 4 classes, 3 phyla and 122.1 inds./m2 in experimental area and control areas were 14 species belonged to 11 families, 6 orders, 4 classes, 3 phyla and 1546.5 inds./m2. From the mine leachate analysis, a high concentration of Cu, Zn, Cd, and Pb was detected, and their levels of pH was measured to be low and their Electric conductivity was high. Spearman's rank correlation coefficient between species number and physico-chemical factors (pH, electric conductivity, Cu, Zn, Cd, Pb) had significant correlations.

Dredging effects of check dam on benthic macroinvertebrate communities of mountain stream

Bong Sung Kim[1], Heon Ho Lee[2], Eul Won Seo[3], Jong Eun Lee[4]

[1]Andong National University, Republic of Korea, [2]Yeungnam National University, Republic of Korea, [3]Andong National University, Republic of Korea, [4]Andong National University, Republic of Korea

This study was conducted for determining the dredging effects of check dam on benthic macroinvertebrate communities. The check dams were surveyed before and after dredging from mountain streams of Yecheon-gun, Yeongju-si and Bonghwa-gun. Sampling was taken at upper and down from 3 experimental sites and 2 control sites during May to August 2011. The identified species before dredging were 38 belonged to 23 families, 10 orders, 5 classes, 4 phyla and 1575.3 inds./m2, but after dredging it has decreased to 21 species belonged to 16 families, 7 orders, 4 classes, 3 phyla and 1055.6 inds./m2. The microhabitat damage of benthic macroinvertebrates occurred at experimental sites after dredging of check dams led to reduction of an average of 38% species. In general, diversity indeces and richness indeces decreased after dredging; however, dominance indeces increased. In the upper stream of experimental sites, the microhabitat damaged and became pool due to dredging. Also, the river bed became simply due to the sedimentary matter being finer than sand and silt. As a result, composition of functional feeding groups and functional habit groups were relatively simpler at upper stream and the degree of community differences was greater between upper and down stream. Community stability by survey, an environment of water system in experimental area started to be somewhat destroyed, after dreding, it is shown that both species in I area which have great ability of resistance and recovery and species in III area which live in relatively stable water system decreased a little.

The influence of dam construction on benthic macroinvertebrate communities of down stream

Bong Sung Kim[1], Eul Won Seo[2], Jong Eun Lee[3]

[1]Andong National University, Republic of Korea, [2]Andong National University, Republic of Korea, [3]Andong National University, Republic of Korea

This study was conducted for determining the influence of dam construction on benthic macroinvertebrate communities of donwnstream. Sampling was taken at 5 experimental sites in downstream areas of Gunwi dam(1 site), Yecheon pumped storage power plant's upper dam(2 sites) and lower dam(2 sites) in Gyeongsangbuk-do of Korea. The benthic macroinvertebrate communities of these dams were surveyed during March 2008 to October 2011. The habitat damage of benthic macroinvertebrates occurred at the experimental sites during dam construction activities and led to a reduction of the number of species and individuals. In general, species diversity indices and richness indices decreased every year; however, dominance indices increased at experimental sites. Composition of filtering collectors increased each year and Hydropsychidae spp. which have greater ability of resistance and resilience and belong to filtering-collectors increased each year. Biological water quality evaluation using the ESB and BIBI was found that decline annually. Spearman's rank correlation coefficient between biological attributes and water quality parameters had significant correlations, particularly in SS and TP. It was found that SS and TP played an important role in structuring benthic macroinvertebrate communities. In conclusion, this study found that disturbances caused by dam construction activities had negative effects on benthic macroinvertebrate communities thus leading to suspended soils occurrence at stream ecosystem.

Edge effect of ground beetles in secondary forests

Jong-Kook Jung[1], Seung Tae Kim[2], Sue Yeon Lee[3], Joon-Ho Lee[4]
[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]Seoul National University, Republic of Korea

We examined the edge effect on ground beetle assemblage in the edge of secondary forests in Hwaseong-si, Gyeonggi-do. Nine secondary forests were selected from highly fragmented urban landscape, and ground beetles collected by pitfall traps during 14 June to 9 November, 2011. A total of Eighty-one pitfall traps were installed along forest interior (+20m)—forest edge (0m)—forest exterior (-20m) gradients in each secondary forest. The species richness was rather higher in forest exteriors (ANOVA, with Tukey's test, F2, 77=0.03, P=0.9670), while abundance was significantly higher in forest edges and forest interiors (F2, 78=6.19, P=0.0032). Non-multivariate dimensional scaling showed a significant difference between forest exteriors and forest edges/forest interiors (Stress=0.13), suggesting that all three habitats had a distinct ground beetle assemblage (ANOSIM, Global R=0.314; P=0.001). By two-way indicator species analysis, Dolichus halensis halensis was an indicator species for the habitat of forest exteriors, while Synuchus cycloderus was an indicator species for forest edge and forest interiors. Because secondary forests in our study had a few forest species, forest edges in our study sites did not showed high species richness possibly. Nevertheless, conservation and management of the edge of secondary forests are important, because forest edges generally provide habitats for overwintering and reproduction of many predaceous arthropods, especially ground beetles.

Temperature effects on development on overwintering *Sericinus montela* Gray (Lepidoptera: Papilionidae) pupa

Jeong Joon Ahn[1], Kang Woon Lee[2], Dong Jae Lee[3], Chuleui Jung[4]

[1]Andong National University, Republic of Korea, [2]Holoce Ecosystem Conservation Research Institution, Republic of Korea, [3]Holoce Ecosystem Conservation Research Institution, Republic of Korea, [4]Andong National University, Republic of Korea

The dragon swallowtail, Sericinus montela Gray (Lepidoptera: Papilionidae), is an important endemic species of Korea because the risk of extinction and habitat loss are increased by human activity including agriculture (cropland, pasture, irrigation, and pesticides), and urbanization. S. montela distributed from central China to the Amur and Ussuri regions. S. montela larvae feed on Aristolochia contorta (Aristolochiaceae). The lower developmental threshold and thermal constants of S. montela overwintering pupae were studied at four different constant temperatures (15, 20, 25 and 30°C) with photoperiod 10:14 (L:D). The lower developmental thresholds of female, male and both sexes combined were 12.38, 12.16, and 12.37°C, respectively. The developmental time of overwintering pupae decreased with increasing temperature between 15 and 30?C. Thermal constants of female, male and both sexes combined were 220.26, 192.31, and 200.18DD, respectively. The relationship between the developmental rate and temperature was fitted by linear and five nonlinear developmental rate models (Logan 6, Lactin 1, 2 and Briere 1, 2). The adult emergence variation of overwintering pupae was described by the two-parameter Weibull distribution model. The temperature-dependent adult emergence model of S. montela developed in this study could be used to develop the full-cycle phenology model of S. montela and applied to understand the effects of climate change on the emergence distribution of overwintering pupae.

Cold tolerance of overwintering eggs of *Lycorma delicatula* (White) (Hemiptera : Fulgoridae)

Marana Park[1], Joon-Ho Lee[2]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea

Lycorma delicatula is an important invasive pest in Korea. Overwintering is a key element of its life history, having large proportion of the life cycle (e.g. 6~7 months/year). In this study, we investigated the seasonal change of cold tolerance on field collected eggs of L. delicatula. Egg collection was made five times, approximately in monthly intervals, in Cheonan from 22 November, 2011 to 1 April, 2012. To examine the effect of cold acclimation, eggs were chilled for 1 week at 1 ℃. Control group was not chilled. For both groups, eggs were treated by the combinations of different temperatures (-5℃, -10℃, -15℃ and -20℃) and exposure time (1hr, 6hr, 12hr, 24hr, 3days, 5days, 7days and 10 days) at each sampling date. Cold tolerance ability showed the temporal changes during the winter season. Egg hatching rate was increased by cold acclimation. Critical temperature appears around -20 ℃ because all eggs treated at -20℃ failed to hatch. For field validation, we collected eggs from six different locations on 22~25 February in 2011 and collected eggs were placed at 25℃. There was significant correlation (r=0.975) between egg hatching rate and the mean low temperature from January 1 to February 28.

Community analysis based on functional feeding groups of benthic macro-invertebrates in Mankyeonggang(R.)

Yong-Lak Jeon[1], Seong-Joon Park[2], Young-Jun Park[3], Byung-Jin Kim[4]

[1]Wonkwang University, Republic of Korea, [2]National Institute of Environmental Research, Republic of Korea, [3]National Institute of Environmental Research, Republic of Korea, [4]Wonkwang University, Republic of Korea

This study is executed to obtain basic data to manage the water quality data of the Mankyeonggang(R.) systematically and to evaluate the biological effect of water quality of the tributary stream to the main course of the Mankyeonggang (R.). Collecting was executed at 7 sites of the main stream (2 upper streams, 4 mid streams, and 1 down stream) and 4 sites of tributary stream (Soyang, Jeonju, Iksan, and Top stream) from May to September 2009. It was also executed for quantitative and qualitative analysis of species diversity of benthic macro-invertebrates of community structure, local ecological characteristics and climate change using the collection, which was collected at the whole investigation sites. A total 114 species of benthic macro invertebrates in 55 families, 19 orders, 7 classes, and 4 phyla were collected during the field surveys. The result of EPT index value showed 44.7%, 51 species of EPT taxa, and it means that the stream ecosystem of Mankyeonggang (R.) is comparatively clear and healthy. Analysing FFG, predator was 37%, which was the highest. Then gathering-collector was 27%, filtering-collector was 15%, scraper was 11%, shredder was 6% , and plant-piercer was 4%. The cluster analysis of aquatic insects lists of species were executed using the similarity index. Therefore, they were divided into 2 groups (A and B), which were A-1(S1), A-2(S2~S7) and B(S8~11).

Keywords:*Functional Feeding Groups, Similarity Index, Cluster Analysis, EPT Index.*

Insects diversity by habitat types in Middle Inland of DMZ, Korea

Seong-Joon Park[1], Jung-Hyo Lee[2], Seung-Hwan Oh[3], Byung-Jin Kim[4]

[1]National Institute of Environmental Research, Republic of Korea, [2]National Institute of Environmental Research, Republic of Korea, [3]Korea National Aboretum, Republic of Korea, [4]Wonkwang University, Republic of Korea

This study was intended to understand the insects diversity and forest in DMZ(de-militalized zone) , and provide data and information required to preserve living creatures and geological management, and basic information for the management and preservation policies of insect diversity in DMZ. This study has surveyed insect diversity by habitat types in Middle Inland of DMZ, KOREA from 15 to 19 September, 2009. Totally there were 128 species belonging to 53 families of 10 orders and among them, 7 endemic species, 3 management of exotic species and 25 designated species were showed. The highest was 26 species of Hemiptera (20.31%) and then next are 22 species of Coleoptera (17.19%) and 20 species of Hymenoptera (15.63%) respectively. Dominant species are Ceracris nigricornislaeta (Bolivar) (0.152%) in S1, Menida violacea Motschulsky (0.218%) in S2, Stomorhina obsoleta (Wiedemann)(0.171) in S3, Ducetia japonica (Thunberg)(0.212%) in S4, Oedaleus infernalis Saussure (0.178%) in S5, Sepedon aenescens Wiedemann (0.268%) in S6, Adelphocoris triannulatus (Stal)(0.257) in S7 and Ricania taeniata Stal (0.150) in S8 site. The diversity (H') and richness (RI) of insects at the survey areas as S2 (H'=3.461, RI=9.64), S3 (H'=3.457, RI=9.18) and S1 (H'=3.447, RI=8.88) were higher than in the others and the lowest in S8 (H'=2.790, RI=5.341). But the highest species evenness index (EI) occurred in S8(0.985).

Understanding of diversity and remarkable insects in urban green space - Botanic garden of Wonkwang University, South Korea

Soeng-Joon Park[1], Min-Ho Lee[2], Jae-Won Kim[3], Eui-Jeong Hong[4], Yong-Lak Jeon[5], Ju-Chang Yoon[6], Jin-Yung Kim[7], Byung-Jin Kim[8]

[1]National Institute of Environmental Research, Republic of Korea, [2]Wonkwang University, Republic of Korea, [3]Wonkwang University, Republic of Korea, [4]Wonkwang University, Republic of Korea, [5]Wonkwang University, Republic of Korea, [6]Wonkwang University, Republic of Korea, [7]Wonkwang University, Republic of Korea, [8]Wonkwang University, Republic of Korea

This study was intended to see the insect diversity in Urban Green Space, special habitats in university campus, and provide data and information required to preserve living creatures and geological management, and basic information for the management and preservation policies. This study has surveyed insect diversity by habitat types in the botanic garden of Wonkwang university, Iksan, Jeonbuk, South Korea from September, 2010 to September, 2011. During the research period, a total of 209 species were observed, 78 families of 11 orders. Among them, 1 was a management of exotic species and 32 was designated species. The highest was 76 species of Coleoptera (36.36%) and next was 46 species in Hemiptera (22.01%), 24 species in Diptera (11.48%), and 16 species in Hymenoptera (7.66%) respectively. The largest number of species was observed in September, 2010, and the highest was also observed in S4. The diversity index (H') and richness index (RI) of insects at survey area as S4 (H'=3.344, RI=9.257) were higher than in the others and the highest species evenness index(EI) occurred in S1 (0.985). But the lowest was in S3 (H'=2.428, RI=4.307, EI=0.832).

Why we need long-term biodiversity monitoring? A case study of macromoths in Mt. Jirisan, a Korea's Long-Term Ecological site

Jeong-Seop An[1], Sang-Hyun Na[2], Jin Lee[3], Sei-Woong Choi[4]

[1]Mokpo National University, Republic of Korea, [2]Mokpo National University, Republic of Korea, [3]Mokpo National University, Republic of Korea, [4]Mokpo National University, Republic of Korea

Mount Jirisan is the largest (440 ㎢) and highest (1,915 m) national park in mainland of South Korea. The vegetation of mount Jirisan is divided into three main zones: warm temperate (200-300 m in southern aspects), cool temperate (400-1,400 m) and subalpine (> 1,400 m). Macromoths, a major herbivore in forest ecosystem were sampled at six sites to understand ecological effect of vegetation community structure in different elevation. A light trap consisting of a 22-watt ultraviolet light with a 12 V battery was employed once a month from May to October from 2005 to 2010. In total, 20,711 individuals in 922 species of 14 families of macrolepidoptera were collected. Estimated species richness with Chao 1 was 1,105 species. The family Noctuidae (417 species) was the most species-dominant group, followed by Geometridae (307 species) and Notodontidae (59 species). Monthly change in the mean number of species and individuals showed a hump-shaped pattern with the peak at July. Unlike monthly change of richness and abundance, the yearly change was inconsistent: the highest species richness with 504 species was 2008 while the lowest with 359 in 2010; the highest abundance was 5,050 in 2006, while the lowest with 2,376 in 2005. The causal factor for this inconsistent yearly change was unknown. However, the long-term monitoring of moths may reveal the pattern and process of population change of moths according to vegetation and environmental changes.

Inner-tree distribution of pinewood nematode, *Bursaphelenchus xylophilus* and its vector, *Monochamus saltuarius* in *Pinus koraiensis* in South Korea

Chan Sik Jung[1], Yil Sung Moon[2], Chul Su Kim[3], Jae Soon Kang[4]

[1]Korea Forest Research Institute, Republic of Korea, [2]Korea Forest Research Institute, Republic of Korea, [3]Korea Forest Research Institute, Republic of Korea, [4]Korea Forest Research Institute, Republic of Korea

After pine wilt disease (PWD) at Korean white pine, Pinus koraiensis has been first reported in the middle area of South Korea in 2006, it spread rapidly to the nearest area. However, we have little information about biological characteristics and pathological mechanisms of PWD on P. koraiensis compared with PWD on P. densiflora. We selected 14 of dead P. koraiensis in PWD damaged area and analyzed the inner-tree distribution of Bursaphelenchus xylophilus and the entrance holes of Monochamus saltuarius. Bursaphelenchus xylophilus were detected from 12 dead pines. There was no statistical significance between height or direction of wood extraction and the distribution of Bursaphelenchus xylophilus. The entrance holes of M. saltuarius were concentrated on 5 dead pines and the maximum number of entrance holes in individual tree was 543. It is considered that the event of spawning of M. saltuarius adult and entrance of hatched M. saltuarius larvae to wood are dependent on the time of death of host pine trees. The entrance holes were frequently found in a southward direction. That implicated that M. salutuarius larvae prefer relatively weak woody parts to enter easily. The relation between the thickness of bark of P. koraiensis and the frequencies of entrance holes of M. saltuarius was not observed.

From 2010 to 2012, 10 institutions have been studying Sporadic and major Insect Pests in Crops to build surveillance system of National Pest Management System(NPMS). This studies were conducted on pepper greenhouse in Goesan-gun, Eumseong-gun and Cheongju-city of Chung-buk Province to investigate the seasonal occurrence of sweetpotato whitefly and western flower thrips. The 5 yellow trap(10×15cm) per site were used every 10 days from May 1 to October 10. In red pepper, the population density of Bemisia tabaci was increased after early-August and the caught number per trap was recorded over 100 adults after early-september. The population density of Frankliniella occidentalis was achieved the peak during early and mid-july and then decreased.

Seasonal occurrence of *Metcalfa pruinosa* (Say) in Chungbuk Province and establishment of optimal control timing

Ki-Su Ahn[1], Myung-Kyu Song[2], Kyeong-Hee Lee[3], In-Gyu Song[4], Gil-Hah Kim[5]

[1]Chungcheongbuk-do Agriculture Research and Extension Services, Republic of Korea, [2]Chungcheongbuk-do Agriculture Research and Extension Services, Republic of Korea, [3]Chungcheongbuk-do Agriculture Research and Extension Services, Republic of Korea, [4]Chungcheongbuk-do Agriculture Research and Extension Services, Republic of Korea, [5]Chungbuk National University, Republic of Korea

This study was investigated the seasonal occurrence of Metcalfe pruinosa (Say) in Chungbuk province and established the optimal control timing. Population densities of nymph and adults were investigated and egg hatching period and oviposition period was examined from three locations (Cheongwon, Jincheon, Eumseong area). Egg hatching period was investigated. The first day of egg hatching observed on May 25, the day of peak egg hatching was on May 29, and the perfect accumulative egg hatching ratio was on Jun. 13. Oviposition period of M. pruinosa female was observed the cut branch (cut within 10 cm length, 1 cm dia.) of oak tree, an althea, and an acacia under stereoscope. The first oviposition was observed at Jul. 28 and continually increased until late-Sept. with sharply increased at mid-Aug. Population density of M. pruinosa nymph was observed the cut branch (cut within 30 cm length, 1 cm dia.) of oak tree, an althea, an acacia, and pear tree. Population density began decreased showing after highest density with 25.3 (Jul. 1). The adult was first appeared at Jul. 11 and showed highest population density with 13.1 (Aug. 4) and then continuously decreased.

Stress response to acoustic stimuli in an aphid: A behavioral bioassay model

Yerim Lee[1], Hyojoong Kim[2], Yikweon Jang[3]

[1]Ewha Womans University, Republic of Korea, [2]Ewha Womans University, Republic of Korea, [3]Ewha Womans University, Republic of Korea

The green peach aphids, Myzus persicae (Sulzer), feed consistently and regularly throughout all stages of nymphs and adult. That is, honey dew production (HDP), which indicates a state of feeding, occurs at regular intervals within a given stage, and moving (MV), which interrupts feeding, tends to occur scarcely. We used these behaviors to test whether the sound stimuli acted as a stress in this species. We conducted the playback experiment in which acoustic stimuli with a combination of five frequency (100, 500, 1000, 5000, and 10000 Hz) and three intensity levels (66, 78, 90 dB SPL) were presented to all stages of aphids. Under all acoustic stimuli, HDP occurred less often, and MV occurred more often and longer. The results of two-way multivariate ANOVA showed that the stimulus frequency was a significant factor for variation in aphid behaviors in the playback experiment. However, there was no intensity effect on aphid's behavior. Based on the electrical penetration graph experiment, aphid feeding was frequently stopped and lasted only for short durations under acoustic stimuli. The results of both experiments demonstrated that the acoustic stimuli were effective in inducing feeding suppression in this species. Thus, the acoustic stimuli may be a stressor in the green peach aphid. Furthermore, the behavioral bioassay employed in this study may be used to assess the effect of various stressors on aphids.

A study on research history and distribution of *Drosophila suzukii*

Youngjin Kim[1], Deuk-Soo Choi[2], Youngho Cho[3], Jinyoung Park[4], Jong-Chul Jeong[5], Sang-Ho Nam[6]

[1]Daejeon University, Republic of Korea, [2]Animal, Plant and Fisheries Quarantine and Inspection Agency (QIA), Republic of Korea, [3]Daejeon University, Republic of Korea, [4]Kyungpook National University, Republic of Korea, [5]Korea National Park Service, Republic of Korea, [6]Daejeon University, Republic of Korea

Although the damage by the Drosophila suzukii (Spotted wing drosophila) was reported in Incheon in 1935 for the first time in Korea, the damage on fruit farm was not reported afterwards. In the wild conditions excluding fruit farm, reports on the spotted wing drosophila have been continuously made through the local distribution of drosophila. Jung (1958) reported the emergence of the Drosophila suzukii in 10 palces in South Korea, Lee(1987) in Muju-gun in Jeollabuk-do and Gyeryongsan in Chungcheongnam-do, Lee and Kim(1987) in 11 mountains including Mt. Halla, Kim et al.(1992) in Mt. Sori in Gyeonggi-do, Lee et al.(1993) in Mt. Chiak in Gangwon-do, Kim et al. (1997) in Gyeongsan and Jinju Neuk-do area. Additionally, Lee(1966) recorded 48 areas in the nation showing that the Drosophila suzukii is distributed in most of the areas in Korea. This study was performed from September 2011 to July 2012 to identify the distribution of the Drosophila suzukii using Drosophila suzukii traps. From the result, it was found that the Drosophila suzukii emerged in 20 points including Jeju-do and the outbreak time and outbreak concentration of Drosophila suzukii by time were identified.

A study on host plant of *Drosophila suzukii*

Youngjin Kim[1], Youngho Cho[2], Deuk-Soo Choi[3], Jinyoung Park[4], Jong-Chul Jeong[5], Sang-Ho Nam[6]

[1]Daejeon University, Republic of Korea, [2]Daejeon University, Republic of Korea, [3]Animal, Plant and Fisheries Quarantine and Inspection Agency (QIA), Republic of Korea, [4]Kyungpook National University, Republic of Korea, [5]Korea National Park Service, Republic of Korea, [6]Daejeon University, Republic of Korea

Drosophila suzukii (Spotted wing drosophila) is originated from Japan and is constantly identified in Asia such as China and Korea, North America such as USA and Canada, and Europe such as Italy, France and Spain. In particular, in USA it brought economic damage such as 20% reduction of the harvest of the berries in 10 places in USA after 2008. Drosophila suzukii is identified as the species doing harm on the various fruits including berries. In this study, the host plants of the Drosophila suzukii were identified. The host plants of the Drosophila suzukii known up to now were 40 species in 12 families such as 25 species in Rosaceae, 1 species in Ericaceae, 1 species in Elaeagnaceae, 1 species in Sapindaceae, 2 species in Caprifoliaceae, 3 species in Moraceae, 1 speices in Cornaceae, 1 species in Cornaceae, 3 species in Vitaceae, 1 species in Ebenaceae, 2 species in Actinidiaceae. Based on the information of the aforementioned host plant information, inoculation elements were performed on the grapes, cherries and blueberries cultivated in Korea and the results are reported here.

Occurrence patterns, life cycle and its environmental friendly control of *Pochazia* sp. in the Apple Orchard

Shin Hyuk Jo[1], Min Woo Park[2], Sae Hee Kim[3], Hye Ri Kwon[4], Mi Ja Seo[5], Yong Man Yu[6], Young Nam Youn[7]

[1]Chungnam National University, Republic of Korea, [2]Chungnam National University, Republic of Korea, [3]Chungnam National University, Republic of Korea, [4]Chungnam National University, Republic of Korea, [5]Chungnam National University, Republic of Korea, [6]Chungnam National University, Republic of Korea, [7]Chungnam National University, Republic of Korea

Leafhopper wings (Pochazia sp.) are occurred areas at Gong-ju, Ye-san, Gu-re, Soon-chang, Go-yang and throughtout the country from 2009. Apples, persimmons, chestnuts, schisandra chinensises, blueberries, and raspberries etc. are known as host. Leafhopper wings which are pests with mouth types for sucking mainly suck sap from leaves and branches of woody plants. After hatching in late May, nymphs were at the end of July and in early September adults were the peak occurrence. Damage by oviposit is more serious than feeding damage by nymphs and adults in apple orchards. Because the adult females through ovipositor lay eggs in old branches after stripped its barks. In addition, according to survey for life history during indoor rearing at 25℃, developmental periods of each instar took average 9.6 days and adults took average 51 days from egg stage. The environmental friendly control was used plant extracts that were toosandanine, oxymathrin, eugenol, veratrine, rotenone, matrine, neem oil, tobacco leaf and emodin. Active ingredient was 0.3%, and diluted 500, 1000 and 2000 times for use. Extracts of matrine and rotenone were showed a relatively high insecticidal activity against young nymphs.

A study on the conservation of butterflies in South Korea included in IUCN Redlist

Minjoo Choi[1], Youngho Cho[2], Yong-Gu Han[3], Youngjin Kim[4], Tae-geun Kim[5], Jong-Chul Jeong[6], Sang-Ho Nam[7]

[1]Daejeon University, Republic of Korea, [2]Daejeon University, Republic of Korea, [3]Daejeon University, Republic of Korea, [4]Daejeon University, Republic of Korea, [5]Korea National Park Service, Republic of Korea, [6]Korea National Park Service, Republic of Korea, [7]Daejeon University, Republic of Korea

The IUCN composed the SSC in 1949 and thereby grasped the extinction and reduction of species existing on earth and the causes and set a guideline for the scientific and objective selection of endangered species. It framed the Redlist by classifying the extinct or endangered species with that as the criteria and is recommending protecting them worldwide. However, Korea only has designated the national endangered species and is protecting and managing them, and the protection of butterflies in Korea included in IUCN Redlist has not been conducted yet. Therefore, this study aims to grasp the present condition of distribution of the butterflies in Korea included in the IUCN Redlist and to present a plan for conservation of them in Korea as they are endangered worldwide. The samples possessed by 22 colleges and institutions in Korea were examined since March, 2008 until August, 2009 in order to investigate the records of distribution from the past. The recorded species in the Korean Peninsula belonging to the Redlist of IUCN are 5 species in total of Coenonympha oedippus, Maculinea teleius, Maculinea cyanecula, Maculinea arionides and Lycaena dispar and are classified as the stage of Lower Risk/near threatened. Maculinea cyanecula was excluded from this research because this species habitats are restricted to North Korea only. As a result of the research on the 4 species, 12 individuals of Maculinea teleius, 25 individuals of Coenonympha oedippus, 52 individuals of Maculinea arionides, and 333 individuals of Lycaena dispar were identified.

An integrative approach to species delimitation in three closely related cricket species (Genus *Loxoblemmus*)

Jaeha Ahn[1], Gilsang Jeong[2], Yikweon Jang[3]

[1]Ewha Womans University, Republic of Korea, [2]Ewha Womans University, Republic of Korea, [3]Ewha Womans University, Republic of Korea

Selection against costly reproductive interaction is most likely to occur between closely related species in sympatry. Then, the divergence in sexual traits for mate recognition is expected to be more conspicuous than are divergences in neutral traits such as other morphological characteristics or molecular sequences. Cricket songs are species-specific and are used for species recognition and mate choice. Three Loxoblemmus cricket species occur sympatrically throughout Korea: L. doenitzi, L. campestris and L. equestris. The horn-headed cricket, L. doenitzi, is morphologically distinguished from the other two species, whereas L. campestris and L. equestris are morphologically very similar. We predicted that calling songs of L. campestris and L. equestris were more differentiated from each other than each from that of L. doenitzi. To test this prediction, we used an integrative approach by comparing the divergences of three types of data: morphology, calling song, and genetic sequence. Because there was no reliable morphological character for species identification, we started the analyses with L. doenitzi and the L. campestris/equestris complex. As expected, the distributions of measured morphological characters did not discriminate between L. campestris and L. equestris. However, the analysis of calling songs clearly separated the L. campestris/equestris complex into two groups. Furthermore, the divergence of mitochondrial COI was consistent with that of calling songs in the L. campestris/equestris complex. The genetic sequence analyses revealed that L. doenitzi diverged off earlier from the other two species. These results suggest that processes of sexual selection may have driven the speciation in the Loxoblemmus complex.

Population genetics study of the lantern fly, *Lycorma delicatula* (Hemiptera: Fulgoridae): Invasion route from China to Korea

Hyojoong Kim[1], Minyoung Kim[2], Sangwook Park[3], Yerim Lee[4], Seunghwan Lee[5], Kai Shi[6], Junhao Huang[7], Heungsik Lee[8], Ki-Jeong Hong[9]

[1]Kunsan National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]Seoul National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Zhejiang A&F University, China, [7]Zhejiang A&F University, China, [8]Animal, Plant and Fisheries Quarantine and Inspection Agency, Republic of Korea, [9]Animal, Plant and Fisheries Quarantine and Inspection Agency, Republic of Korea

Lycorma delicatula (White 1845), which has been recently introduced into Korea, is a notorious pest on grapes. This invasive insect has rapidly spread throughout central and southern Korea. To compare genetic characteristic and differentiation between Lycorma delicatula populations, we collected samples in East Asia. Between 2010 and 2011, we collected totally ca. 800 individuals in 36 populations from Beijing, Tianjin, Shandong, Jiangsu, Shanghai, Zhejiang in China, and from Ishikawa in Japan. First we analyzed representative populations in Korea, China, and Japan using ND2 and ND6 sequences by neighbor-joining method. As results, the populations of Shanghai, Beijing, Tianjin, and all Korean regions shared a same haplotype. Second we analyzed population genetics using 12 microsatellites. PCA and STRUCTURE tests showed that Shanghai likely is the origin of the Korean L. delicatula populations. Based on GeneClass2 assignment results, Seoul and Incheon in capital area, and Nonsan and Buan in central area were inferred to the first invading regions within Korea, from where L. delicatula then dispersed to other regions. We tested four scenarios to confirm the invasion route using Approximate Bayesian Computations. As results, L. delicatula originated from Shanghai invaded into both capital and central areas at the same time. In addition, we tested 762 individuals combining the former dataset with additional samples collected in 2006-2009. The structure analysis resulted in that L. delicatula populations occurring in Korea independently were introduced at least three times.

Population genetic structure of the soybean aphid from Asia and North America based on microsatellites

Hyojoong Kim[1], Minyoung Kim[2], Kim A. Hoelmer[3], Seunghwan Lee[4]

[1]Kunsan National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]United States Department of Agriculture, U.S.A., [4]Seoul National University, Republic of Korea

The soybean aphid, Aphis glycines Matsumura, was recently introduced from Asia into North America (NA) where it has become a serious pest of soybeans. This invasive pest has rapidly spread throughout the midwestern United States and southern Canada since 2000. We examined 593 individuals obtained from 24 different collections in USA, Korea, China, and Japan using eight microsatellite loci. Based on analysis of multilocus genotype, gene diversity and number of alleles in NA were averaging 0.40 and 2.70, whereas in Asia averaging 0.55 and 4.32, respectively. The factorial correspondence analysis displayed that some Korean populations were closely related to the NA populations. Structure analysis resulted in two conspicuous clusters, NA and Asia, as the most likelihood number of clusters (K=2). Bayesian assignment tests revealed that Osan and Milyang populations in Korea were most likely assigned to the NA populations. Bottleneck test did not show significance of genetic bottleneck in all populations. We also discuss the invasive history of the soybean aphid in light of population genetics.

Foliar aphid feeding recruits rhizosphere bacteria and primes plant immunity against pathogenic and non- pathogenic bacteria in pepper

Boyoung Lee[1], Soohyun Lee[2], Choong-Min Ryu[3]

[1]Korea Research Institute of Bioscience and Biotechnology/University of Science and Technology (UST), Republic of Korea, [2]Korea Research Institute of Bioscience and Biotechnology, Republic of Korea, [3]Korea Research Institute of Bioscience and Biotechnology, Republic of Korea

Plants modulate defence signalling networks in response to different biotic stresses. The present study evaluated the effect of a phloem-sucking aphid on plant defence mechanisms during subsequent pathogen attacks on leaves and rhizosphere bacteria on roots. Plants were pretreated with aphids and/or the chemical trigger benzothiadiazol (BTH) seven days before being challenged with two pathogenic bacteria, Xanthomonas axonopodis pv. vesicatoria (Xav) as a compatible pathogen and X. axonopodis pv. glycines (Xag) as an incompatible (nonhost) pathogen. The aphid population was reduced by BTH pretreatment and by combination treatment with BTH and bacterial pathogens in a synergistic manner. Analysis of the expression of the defence-related genes Capsicum annum pathogenesis-related gene 9, chitinase 2, SAR8.2 and lipoxygenase1 revealed that aphid infestation resulted in the priming of the systemic defence responses against compatible and incompatible pathogens. Conversely, pre-challenge with the compatible pathogen Xav on pepper leaves significantly reduced aphid numbers. Aphid infestation increased the population of the beneficial Bacillus subtilis GB03 but reduced that of the pathogenic Ralstonia solanacearum SL1931. The expression of defence-related genes in the root and leaf after aphid feeding indicated that the aboveground aphid infestation elicited salicylic acid and jasmonic acid signalling throughout the whole plant. The findings of this study show that aphid feeding elicits plant resistance responses and attracts beneficial bacterial populations to help the plant cope with subsequent pathogen attacks.

Life table-based computer simulation of population dynamic of *Spodoptera litura*. (F.) fed on groundnut (Arachis hypogaea) leaves under different condition

Shu-Jen Tuan[1], Chung-Chieh Lee[2], Hsin Chi[3]

[1]National Chung Hsing University, Taiwan, [2]National Chung Hsing University, Taiwan, [3]National Chung Hsing University, Taiwan

Spodoptera litura (F.) is the most destructive leaf-defoliating pest of peanuts (Arachis hypogaea) in Taiwan. To accurately simulate the population dynamics of S. litura, life table data, using the age-stage, two-sex life table, were collected at constant temperature 25ºC in the laboratory, and outdoors under field conditions in the spring and fall of 2010. Results showed that there were significant differences in developmental times, survival rate, fecundity, and hatch rate under different conditions. The shortest immature stage occurred in fall (19.2 d), while the longest was in spring (28.4 d). At 25℃, both male and female adults lived longer than adults under field conditions. The mean generation time was the shortest in fall (34.5 d). The preadult survival rates in spring (39.9%) and fall (53.3%) were lower than the rate observed at 25℃ (84.6%). The mean fecundity of S. litura was 3548, 3452, and 3072, at 25℃, in spring, and fall, respectively. The hatch rates were 64.2, 72.2, and 26.0%, respectively. At 25°C, the intrinsic rate of increase (0.1838 d-1), finite rate of increase (1.2017 d-1), and net reproductive rate (963.2 offspring) were the highest among all treatments. Population parameters showed high variability in spring and fall. Because both hatch and survival rates in the field were affected by various unregulated environmental factors, they were lower than those obtained at constant temperature. Our results demonstrate that computer simulation based on life tables collected under both laboratory and field conditions is an important tool for prediction pest emergence.

Life table of *Kolla paulula* (Walker) reared on *Bidens pilosa* L. var. radiata Sch. and *Wedelia triloba* (L.)

Pei Wen Chang[1], Shu-Jen Tuan[2]

[1]*National Chung Hsing University, Taiwan,* [2]*National Chung Hsing University, Taiwan*

Kolla paulula (Walker), the xylophagous leafhopper, was recently identified at the Taiwan Agricultural Research Institute as a potential vector of the xylem-limited bacterium, Xylella fastidiosa (Wells), the causative agent of Pierce's disease and pear leaf scorch disease in Taiwan. The developmental rate, survivorship, reproduction, and life-table parameters of K. paulula reared on mixture of Pilose beggarticks (Bidens pilosa var. radiata) and Trilobate Wedelia (Wedelia triloba L.) were studied using the age-stage, two-sex life table. Experiments were carried out outdoors under naturally fluctuating temperatures from Feb. to Aug. 2011. The total immature development time was 53.0± 4.0 d. The survival rate was observed in the egg stage (81.6%), while the survival rate of other stages was as high as 98%. The adult preoviposition period was 6.9 d, and the mean fecundity was 91.5 ± 39.3 eggs. The adults could survive, on average, 1.5 mo (46.8 ± 16.3 d for females and 50.3 ± 16.7 d for males). The intrinsic rate of increase (r), finite rate of increase (λ), net reproductive rate(Ro), and mean generation time (T) were 0.0473 d-1, 1.0485 d-1, 33.7 offspring, and 74.3 d, respectively.

Locality records of potato tuber moth, *Phthorimaea operculella* (Zeller), distributed in the Korean Peninsula

Min Kwon[1], Juil Kim[2], Young Gyu Lee[3], June Yeol Choi[4]

[1]National Institute of Crop Science, RDA, Republic of Korea, [2]National Institute of Crop Science, RDA, Republic of Korea, [3]National Institute of Crop Science, RDA, Republic of Korea, [4]RDA, Republic of Korea

Potato tuber moth (PTM), Phthorimaea operculella (Zeller), is a cosmopolitan pest, especially in warm temperature and tropical regions where host plants, mostly belong to family Solanacea, are grown. In recent years, the species has been inadvertently occurred in the potato fields of middle areas of Korea. To determine the distribution of PTM, we carried out an extensive survey using sex pheromone traps at 38 sites across the nation during 2009~2011. Delta-typed traps were baited with rubber septa impregnated with commercially available PTM sex pheromone. In each area surveyed, a potato field approximately 0.1~3 ha in size was selected and 2 traps were randomly placed in that field 1 m above ground level. As a result, we confirmed that the range of PTM extended from southern coastal regions to the central regions of the Korean Peninsula. The northern limit of PTM distribution expanded to northern Gyeonggi (Yeoncheon, Gangwha, Gimpo, Paju) and middle Gangwon regions (Goseong, Inje, Pyeongchang) from Gyeongbuk and Chungbuk regions reported first by Choi & Park (1980). Based on these data, we investigated why drastic going northward of PTM happened in Korea. Here is one presumption that a sudden rise in average temperature has occurred during 30 years, from 6.34℃ of 1973 to 7.62℃ of 2007, in the Korean Peninsula.

Investigation the effect of storage of wheat and corn on Mediterranean flour moth based on an Age-Stage, Two-Sex Life Table

Yasaman Moghaddasi[1], Ahmad Ashouri[2], Shirin Parizad[3]

[1]University of Tehran, Iran, [2]University of Tehran, Iran, [3]University of Tehran, Iran

However Ephestia kuehniella is a cosmopolitan pest of stored products, its eggs and larvae are widely used to rear parasitoids and predators. Therefore investigation the effect of storage of wheat and corn on this insect is important particularly economically for mass rearing in insectariums. Most life-table analyses have been concerned only with the female population, however, this moth is not parthenogenetic and both males and females are economically important. Treatments used in this study include equal proportions of corn and wheat flour (48.5%) and 3% yeast: 1- new corn, new wheat; 2- new corn, old wheat;3- old corn, new wheat; 4- old corn, old wheat. Experiment was carried out with 50 replications at controlled conditions. Data were analyzed based on an age-stage, two sex life table model developed by Chi. The results indicate that there is significant difference in mean generation time (T) and the most and the least amount of T respectively were in treatment 2 and 3. But there was no significant difference in other parameters such as the gross reproduction rate (GRR) and the net reproduction rate (R0). Although treatments had different the intrinsic rate of increase (rm) no significant difference was observed. Also the most weight of larvae, pupa and adult and the number of eggs and The lowest percentage of deaths and adult longevity occurred in treatment 1. When the cost is taken into consideration, new corn and wheat is recommended to produce satisfactory quantity and quality of E. kuehniella adults and eggs.

Review of the food plants of Lepidopteran larvae outbreaking in a national park and outbreaking species management

Yong-Gu Han[1], Youngho Cho[2], Youngjin Kim[3], Minjoo Choi[4], Sang-Ho Nam[5]

[1]Daejeon University, Republic of Korea, [2]Daejeon University, Republic of Korea, [3]Daejeon University, Republic of Korea, [4]Daejeon University, Republic of Korea, [5]Daejeon University, Republic of Korea

In this study, lepidopteran larvae outbreaking in a national park and the food plants of these larvae were identified to determine proper management methods. Numerous trees on climbing paths near Donghak Temple and Gap Temple at Mt. Gyeryong National Park were investigated from April to June in 2009, 2010, and 2011. In the survey, it was found that the three species of Alcis angulifera, Cosmia affinis, and Libythea celtis outbreak and utilize multiple food plants in addition to their well-known food plants as noted in the literature. In the case of A. angulifera, it eats a total of 12 species not only of previously known food plants such as Quercus serrata, Weigela subsessilis, Castanea crenata, Celtis sinensis, and Camellia japonica but also Zelkova serrata, Styrax japonicus, and Prunus sargentii. It was also found that C. affinis and L. celtis each had seven species of food plants. The survey results show that they are polyphagous insects that eat a wider range of food plants than previously known. The reasons why insect outbreaks occur remain unclear. They arise, however, when multiple elements are combined and when the diversity of the food plants has a very close relationship with the outbreaking insect. As insect outbreaks generally have detrimental effects on plants and on other species, often disturbing the natural ecosystem, most countries consider outbreaks to be a very sensitive issue. At the same time, in advanced countries such as the USA and in Korea, outbreaks arising in national parks are a major concern.

Brood size and sex ratio regulation in the pupal ectoparasitoid, *Pteromalus apum* parasitizing the Glanville fritillary butterfly, *Melitaea cinxia*

Norio Hirai[1], Saskya Van Nouhuys[2]

[1]*Osaka Prefecture University, Japan,* [2]*University of Helsinki, Finland*

Pteromalus apum is a gregarious pupal parasitoid of butterflies, including the Glanville fritillary butterfly, Melitaea cinxia. We investigated the brood size and sex ratio under 4 different superparasitism situations using M. cinxia pupae as a host. We exposed 1, 2 or 3 female wasps to a host. When a host was exposed to female wasps sequentially, each for 1 hour, the brood size increased with number of females used. The proportion of offspring that was male was 5-7%, with no significant difference between the 3 treatments. Similar trends were observed when a host was exposed to each female wasp for 1 hour, with a 24 h between each. When a host was exposed to 2-3 female wasps simultaneously for 24 hour, both brood size and proportion of the brood that was male increased with the number of females used. Similar results were also obtained when we use Inachis io and Aglais urticae as hosts. Thus, the sex ratios from singly parasitized hosts were strongly biased towards females and did not differ among all the sequential oviposition experiments. But when multiple wasps were with a host at the same time the sex ratio of the progeny increased. This suggests that physical contact among female wasps is primarily responsible for the sex ratio response in this species.

Mosquito fauna in Singapore

Mee Lian Lee[1], Ah Bah Png[2], Siew Yoong Foo[3], Lee Pei Chiang[4], Chee Seng Chong[5], Lee Ching Ng[6], Sai Gek Lam-Phua[7]

[1]National Environment Agency, WHO Collaborating Centre for Arboviruses and their Associated Vectors, Singapore, [2]National Environment Agency, Singapore, [3]National Environment Agency, Singapore, [4]National Environment Agency, Singapore, [5]National Environment Agency, Singapore, [6]National Environment Agency, Singapore, [7]National Environment Agency, Singapore

The Republic of Singapore is a tropical island-city situated 137 kilometres north of the Equator. It comprises of mainland Singapore and its 62 islets. Despite extensive urbanisation, approximately 23% of its land area still remains forested. As a result, Singapore has an abundance of diverse fauna of mosquito where 125 species were reported in 1986. From 2003, Environmental Health Institute (EHI), the mosquito reference centre of Singapore, worked with various stakeholders to collect adults and larvae routinely from vegetated areas on the main and other smaller islands. The information is compiled in a database that is invaluable to our understanding of the diversity, distribution and seasonal trends of mosquitoes. At the same time, specimens (larvae and adults) were carefully curated in EHI. In 2010, 12 species including nine new records were added to this list. Till date, EHI has a collection of over 7000 adults and 900 larval specimens, representing at least 80 mosquito species. This represents the most comprehensive mosquito collection in Singapore.

Responses of Tabanidae (Insecta: Diptera) species to Malaise traps baited with octenol

Mehmet Calik[1], Ferhat Altunsoy[2]

[1]*Anadolu University, Turkey,* [2]*Anadolu University, Turkey*

Adult female Tabanidae species which are blood sucking parasites cause serious problems in terms of medical and veterinary. No fully-effective methods are mentioned on literature to keep Tabanidae species under control. Synthetic and natural attractant including traps are in use on many parts of the world to collect female tabanids. Many attractants may be effective or ineffective under various environmental conditions in different geographic regions for horseflies. Octanol has a effect on many horsefly species behaviours and when used with other phenolic compounds it becomes very effective for this group of insects.. The study was performed on Catacık forests and Hekimda? in Eski?ehir and it emphasize the relationship between traps baited with the octanol and control traps. The results present that Tabanus is the most represented genus with 93,6 % of the total collected tabanids. The chi-squared analyses show that traps baited with the octanol collected 5 times more tabanids than control traps and Tabanus briani (Leclercq, 1962), Tabanus rupium (Brauer 1880) and Tabanus portschinskii (Olsufjev, 1937) species are only determined on the octanol baited traps. Research results were evaluated by comparing with other studies made with octanol. As a result, female tabanidleri to control or minimize their losses in order that there may be an effective method of using with octanol traps.

First record in Egypt of two thrips species infesting cucumber crops

Seham Salah Moursy[1], Abeer Salah El-Din Abdel-Wahab[2], Mohamed Abdel-Kadeir El-Shiekh[3], Salah Eldin Hassan Elnagar[4]

[1]Fac. of Agric.-Cairo University, Egypt, [2]Fac. of Agric.-Cairo University, Egypt, [3]Fac. of Agric.-Cairo University, Egypt, [4]Fac. of Agric.-Cairo University, Egypt

Field survey was made in four successive cucumber plantations (sown on mid April and mid August, 2010/2011) in Giza, Egypt. Direct inspection of weekly leaf samples revealed that two thrips species Chirothrips texanus Andre and Thrips palmi Karny were detected for the first time in Egypt, in addition to Thrips tabaci Lindeman and Frankliniella occidentalis (Pergande). The highest number of thrips species was recorded in August plantations for Thrips tabaci (923 individuals/25 leaves) followed by Ch. texanus (679 individuals/25 leaves). F.occidentalis recorded the lowest number (368 individuals/25 leaves). The present finding updates the list of thrips species in Egypt.

Sequential sampling and population dynamics of *Rhopalosiphum maidis* and *Schizaphis graminum* aphids in Badjgah region (Fars province)

Vajiheh Soltani Ghasemloo
Iran

SEQUENTIAL SAMPLING AND POPULATION DYNAMICS OF Rhopalosiphum maidis and Schizaphis graminum APHIDS IN BADJGAH REGION (FARS PROVINCE) Vajiheh Soltani Ghasemloo1, Maryam Aleosfoor2, Abdolamir Mohiseni3, Mahmood Alichi2, Lida Fekrat4 1College of Agriculture, Shiraz University, Shiraz, Iran. E-mail: v_soltani84@yahoo.com , 2Associated Professors of Plant Protection Department, College of Agriculture, Shiraz University, Shiraz, Iran. 3Associated Professors, Agricultural and Natural Resource Research Center of Lorestan, 4Associated Professors of Plant Protection Department, College of Agriculture, Ferdowsi University, Mashhad, Iran During 2010-2011, fixed precision sequential sampling plans with X shape pattern of movement in the field were investigated for two aphids Rhopalosiphum maidis and Schizaphis graminum, in fields of wheat in Badjgah (Fars province). Based on Dancan test, and RV, the best sample unit was 4 stems. taylor's power law gave a suitable fitness. Since regression line slopes weren't significantly different for S. graminum and R. maidis, comparing both of them by the same Green model was proposed. In precisions of 0.15, 0.25 and 0.3 in Green's fixed- precision method, minimum numbers of samples for R. maidis and S. graminum were 20, 12 and 9, respectively. The numbers of needed samples in Green method with 0.15, 0.25 and 0.3 precision were reduced to 77.8±1.05, 78.3±0.91 and 81.4±0.81, respectively. When the population mean of these aphid was 1.6, 3.86 and 5.62 poroportion of infection in the field was 0.5, 0.75 and 0.85, respectively. Relationship between sample number and plant with aphids showed that sample number reduce with increasing in infection percentage.

Determining the best sample unit in sequential sampling for *Rhopalosiphum padi* (L.) in Badjgah wheat field

Vajiheh Soltani Ghasemloo
Iran

Determining the best sample unit in sequential sampling for Rhopalosiphum padi (L.) in Badjgah wheat field Vajiheh Soltani Ghasemloo1, Maryam Aleosfoor2, Abdolamir Mohiseni3, Mahmood Alichi2, Lida Fekrat4 1College of Agriculture, Shiraz University, Shiraz, Iran. E-mail: v_soltani84@yahoo.com , 2Associated Professors of Plant Protection Department, College of Agriculture, Shiraz University, Shiraz, Iran. 3Associated Professors, Agricultural and Natural Resource Research Center of Lorestan, 4Associated Professors of Plant Protection Department, College of Agriculture, Ferdowsi University, Mashhad, Iran Rhopalosiphum padi is one of the most important aphids in wheat fields of Iran. During 2010-2011, population fluctuation, spatial distribution and fixed precision sequential sampling plans of this aphid was investigated in fields of wheat in Badjgah (Fars province). This aphid attacked wheat fields in the late April and its population peak was seen on April 9th 2011, when the mean temperature and relative humidity were 11.25 ?C and 33.5±5%, respectively. RV results in the fields (bahar cultivar), for 1,2,3,4 and 5 stems calculated 38.1,32.9,29.3,28.7 and 28.62, respectively. 4 and 5 stems did not show any significant difference. The results of RNP analysis for 1,2,3,4 and 5 stems were 6.7,6.1,5.6,5 and 4.5. RV showed that 4 stems was the best choicein proportion 5 stems because it consumed lower time for counting aphids. High RNP showed high efficiency in number of sample or sampling method, but in this project 1 stem had highest RNP, so we can not accept it. At the end the best choice for sampling unit was 4 stems.

Preference of the natal fruit fly, *Ceratitis rosa* to different fruit scents in a choice trial

Makuena Margrett Lebusa[1], Mark Laing[2], Ray Miller[3]

[1]University of Kwazulu-Natal, South Africa, [2]University of Kwazulu-Natal, South Africa, [3]University of Kwazulu-Natal, South Africa

Ceratitis rosa (Natal Fruit Fly) is one of the most economically important pests of citrus fruits throughout the world. The status of C. rosa like other fruit flies as a major pest, is maintained on cultivated fruits because it is more abundant in both cultivated and wild fruits throughout the year. C. rosa has a wide range of hosts including citruses as one of the most preferred cultivated hosts. Fruit fly management aims at deploying Bait Application Technique (BAT) which has been considered to control fruit flies over a large area. This can be achieved by using an "Attract and Kill" approach incorporating attractants in the form of food and pheromones. In this study fruit scents have be used as attractants in a bait station to attract flies to the killing agent. Flies have been introduced to the different fruit scents in a choice experiment to determine the most preferred scent/s and preliminary results have shown that orange scent (Limonene) and banana scent (Isomyl acetate) are the most attractive to the Natal fruit fly. Further trials will be carried out to further test the attractiveness of these scents in fruit fly baits.

Quantifying dispersal of *Trichogramma brassicae* in the tomato fields using diffusion model

Samaneh Soltantoieh[1], Gholamhossein Gharekhanig[2], Ali Mehrvar[3]
[1]University of Maragheh, Iran, [2]University of Maragheh, Iran, [3]University of Shahid Madani, Iran

The study of insect dispersal plays an essential role in estimating the aerial spread of damage caused by a newly invaded pest or the spatial distribution of an useful insect during the active period. Although plenty of studies on trichogramma has been focused on potential of this parasitoids, quantitative knowledge of the movement of trichogramma species is lacking in the field. To fill this gap we intended to study Trichogramma brassicae dispersal using diffusion model. The parasitoids were reared on grain moth eggs, marked using fluorescent powder and released from a central point at 12 different dates from fruit set to harvest and repeated five times. Trap cards were used at distances including 2, 5, 9, 12, 18 and 25m and height 20 Cm from a central releasing point. Parasitized eggs were collected and examined three and six days after release respectively. Non-linear regression was used for estimating the parameters and fitting the models. Accuracy of the estimated parameters was tested according to the default asymptotic 95 % confidence intervals. Indirect method was used for estimating diffusion coefficient (D), R2, migration and mortality (K) and population size (Y) three days after releases. Estimate ranged for (D) from 5.0322-19.2901, R2= 89.2, (K) from 0.0036-0.0976 and (Y) from 1869.14 - 4357.12. Resulted models were compared for different dates. Results revealed the fitness of models for trichogramma dispersal at different dates and for overall experimental time as well as suitability of diffusion model for study of trichogramma dispersal behavior.

A study of the community structures of the dead wood dwelling arthropods

Hyun Jung Kim[1], Hoonbok Yi[2]

[1]Seoul women's univ., Republic of Korea, [2]Seoul women's univ., Republic of Korea

The dead wood?dwelling arthropod communities were surveyed from 2010 April to 2011 October in three areas (Mt. Woonak, Mt. Wolchul, Mt. Jingang). Arthropods were sampled with an vacuum aspirator. Arthropod species were classified regarding their functional association as herbivores, fungivores, xylophagous, saproxylophagous, detritivores, and predators. Arthropod communities with 5 variables were analyzed. We collected 8,792 arthropods during our study (5 classes, 20 orders, 58 families, and 93 species). But larva was not counted. The species richness and abundance of arthropods were increased along with the progress of the decay stages for the conifer and deciduous. The species richness index was increased and the evenness index was shown to be at a lower value at the late decay stage than at the other decay stages. The diversity index (H') in conifer was lower than the deciduous at the early decay stage. The deciduous was lower than the conifer at the decay stage. Arthropod communities of functional groups, except the xylophagous were not different in the variables. Xylophagous increased as the decay stages progressed. The abundance of arthropods and xylophagous were significantly different statistically. Overall, the logs play an important role for arthropods as habitats. Thus, we realize that the dead woods are important as a component factor in the forest. When we come up with forest management measures with these important facts, so that dead wood has a good role in the forest, the arthropod community, the species biodiversity of arthropods and higher predator biodiversity will be more complex and maintainable.

A predictive model for the spring emergence of the pine needle gall midge *Thecodiplosis japonensis* (Diptera: Cecidomyiidae): Applicability of empirical predictive model based on field observations

Youngwoo Nam[1], Mun-Jang Jeon[2], Won Il Choi[3], Sang-Hyun Koh[4]

[1]Korea Forest Research Institute, Republic of Korea, [2]Daegu University, Republic of Korea, [3]Korea Forest Research Institute, Republic of Korea, [4]Korea Forest Research Institute, Republic of Korea

Empirical models based on field observation are often better in practice for predicting field events although phenology models are usually constructed using laboratory temperature-dependent development data. Based field observation in Yeongcheon, Korea from 1986 to 2010, the empirical predictive model for spring emergence of Thecodiplosis japonensis (Diptera: Cecidomyiidae) was constructed. Spring emergence of T. japonensis adults occurred from mid-May to mid-July at Yeongcheon and showed wide spread patterns with annual variation during 1986-2010. The correlation between pooled cumulative proportion of spring emergence versus cumulative degree days, using a selected baseline temperature, was fitted with a Weibull function. By varying the baseline temperature (from 3 to 9 °C at 0.5 °C increments), it was determined that the use of 6.1 °C as the lower temperature threshold of its post-diapause development gave the highest R2, indicating that 6.1 °C was likely to be the lower temperature threshold of T. japonensis. The lower temperature threshold based on field observations was only 0.2 °C higher than that based on laboratory temperature-dependent development data (Son et al. 2007). Also, both degree-day models using the lower temperature threshold based on laboratory and field observation accurately predicted spring emergence of T. japonensis in 2011, suggesting that that estimation of the degree-days needed for post-diapause development could be based on field observations and would be a useful approach to develop a phenology model.

Keywords:*degree-day model, spring emergence, Weibull function, Thecodiplosis japonensis, phenology*

Effect of temperature on development of *Elcysma westwoodi* (Lepidoptera: Zygaenidae) in Korea

Sung-Jae Jeon[1], Sang-Hyun Koh[2], Youngwoo Nam[3], Sang-Gil Lee[4]

[1]Korea Forest Research Institute, Republic of Korea, [2]Korea Forest Research Institute, Republic of Korea, [3]Korea Forest Research Institute, Republic of Korea, [4]Korea Forest Research Institute, Republic of Korea

A tailed zygaenid moth, Elcysma westwoodi (Vollenhoven) has a univoltine with a winter diapause as young larval instars and a summer diapause as prepupa in a cocoon. Temperature has been known to be one of the major regulatory factors of development and initiation of the summer diapause. This study presents a comprehensive summary of development, mortality, and initiation of summer diapause in relation to temperature. The larvae collected in the field divided into three groups based on the distribution of headcapsule widths, which assumed second instar in group A, third instar in group B and forth instar in group C. Regardless of group classification, developmental rates generally increased with increasing temperature from 15 to 25 °C and rapidly decreased to zero at 30 °C. Also, mortality rate for all groups was lowest at 20-25 °C and were 100 % at 30 °C. These results suggest that 25 and 30 °C are the optimum temperature and higher threshold temperature on post-diapause development, respectively. The developmental periods from overwintered larva to initiation of the summer diapause in each groups ranged from 85.5 days at 15 °C to 46.5 days at 27 °C for group A, from 80.3 days at 15 °C to 45.6 days at 27 °C for group B and 74.2 days at 15 °C to 41.9 days at 27 °C for group C. These results suggest that temperature plays an important role in life history traits of E. westwoodi through not only temperature-dependent development, but also through high-temperature inhibition.

Binomial sampling plans for *Aphis gossypii* (Hemiptera: Aphididae) on greenhouse cucumbers

Taek-Jun Kang[1], Joon Ho Lee[2], Jung-Joon Park[3], Kijong Cho[4]

[1]Institute of Horticultural and Herbal Science, RDA, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Korea University, Republic of Korea, [4]Korea University, Republic of Korea

Infestations of Aphis gossypii per leaf on commercial greenhouse cucumbers were determined for developing binomial sampling plans. An empirical PT-m model, , was used to evaluate relationship between the proportion of infested leaves ≤ T aphids per leaf (PT) and mean densities (m). Tally thresholds (T) were set to 1, 3, 5, 7 and 9 aphids per leaf to find appropriate T in cucumber greenhouse system, respectively. Increasing sample size did little effects on the precision of the binomial sampling plan. However, the precision increased with higher tally threshold. The binomial model with T = 5 provided appropriate predictions of mean densities of A. gossypii on greenhouse cucumbers. By results of the binomial model with T = 5 (sample size = 200), wide ranges of densities (1.2 - 222.8 aphids per leaf) could be estimated with precision levels of 0.346 - 0.380 for PT values between 0.15 and 0.96. Binomial models were validated at T = 5 and 7 using twelve independent data sets on different greenhouse cucumbers. Both binomial models were robust and adequately described most of independent sampling data fell within 95% confidence intervals around the prediction model.

Molecular operational taxonomic units (MOTUs) of chironomids (Diptera: Chironomidae) for water quality assessment in Korea

Tae Joong Yoon[1], Min Jeong Baek[2], Jeong Mi Hwang[3], Won Young Choi[4], Yeon Jae Bae[5]

[1]Korea University, Republic of Korea, [2]Korea University, Republic of Korea, [3]Korea University, Republic of Korea, [4]National Institute of Biological Resources, Republic of Korea, [5]Korea University, Republic of Korea

The non-biting midge family Chironomidae is one of the most widely distributed and abundant group of organisms in diverse freshwater habitats. The composition of chironomid larvae has been frequently used as biological indicators of water quality because a wide spectrum of responses to environmental stress is observed. However, there is a fundamental problem with the use of chironomids because species level identification by using chironomid larval morphology is virtually impossible. Therefore, it is suggested that the molecular operational taxonomic units (MOTUs) equivalent to the traditional species level identification could be used for this purpose. This study was conducted to investigate the relationship between MOTUs and the water quality of streams in Korea. The chironomid larvae were collected from diverse reaches in streams and rivers that showed different levels of water quality. The partial mitochondrial DNA cytochrome c oxidase I (COI) genes (ca. 670 bp) were sequenced and analyzed in relation to the water quality. The results showed a close correlation between the chironomid MOTUs and chemical water quality, thus providing species-specific information about the stream environment.

Keywords:*Chironomidae, cytochrome c oxidase I (COI) gene, molecular operational taxonomic unit (MOTU), biological water quality assessment*

Longevity and Life table of the striped fruit fly (*Bactrocera scutellata*) adults on pumpkin flowers

Sung-Wook Jeon[1], Myoung-Rae Cho[2], Taek-Jun Kang[3], Hyeong-Hwan Kim[4], Seung-Jun An[5], Hae Woong Park[6]

[1]National Institute of Horticultural & Herbal Science, Republic of Korea, [2]National Institute of Horticultural & Herbal Science, Republic of Korea, [3]National Institute of Horticultural & Herbal Science, Republic of Korea, [4]National Institute of Horticultural & Herbal Science, Republic of Korea, [5]National Institute of Horticultural & Herbal Science, Republic of Korea, [6]National Institute of Horticultural & Herbal Science, Republic of Korea

Adult longevity and fecundity of the Striped Fruit Fly, Bactrocera scutellata, were studied at 15~33oC with 65% RH and 16L:8D in laboratory. The highest values of longevity was observed at 21oC with the values of 138.0 for male and 131.2 for female, followed by 24oC and 27oC. Adult females of the Striped fruit flies did not oviposit at all below 18oC or over 33oC. The highest value of fecundity was observed at 24℃, being 111.4 eggs. Jacknife life was evaluated from eggs to adults of the Striped fruit flies at 4 different temperatures. There was a negative correlation between Net reproductive rate(Ro) and temperature. Net reproductive rate(Ro) decreased with increasing temperatures, being highest at 21oC. In case of the intrinsic rate of increase per day(rm) and the finite rate of increase per day(λ), there was little difference among temperatures. However, doubling time(Dt) and the mean generation time(To) decreased with increasing temperature.

Mating behavior and attractants of the pumpkin fruit fly, Bactrocera depressa (Tephritidae: Diptera)

Seung-Joon Ahn[1], Kyung San Choi[2], Taek Jun Kang[3], Sung-Wook Jeon[4], Dong-Soon Kim[5]

[1]National Institute of Horticultural and Herbal Science, Republic of Korea, [2]Rural Development Administration, Republic of Korea, [3]Rural Development Administration, Republic of Korea, [4]Rural Development Administration, Republic of Korea, [5]Jeju National University, Republic of Korea

The pumpkin fruit fly, Bactrocera depressa (Tephritidae: Diptera) is one of the most important pests in Cucurbitaceae plants. The mating behavior of B. depressa consisted of: (1) approach, (2) turning, (3) jumping or striking, and (4) copulation. Volatiles that were collected from males during mating showed two active peaks in GC analysis, which are 2-hexanone and 6-Oxo heptanoic acid analyzed by GC-Mass. In a flight-tunnel bioassay, the chemicals induced the approach behavior of females, but the turning or jumping behavior was not observed. In the field trials, however, the chemicals did not show any attraction of B. depressa. Candidate attractants including methyl eugenol, cue-lure, protein sources, pumpkin juice, and pumpkin powder were tested. Unexpectedly, B. depressa showed no response to methyl eugenol and cue-lure, two common attractants in other fruit fly species, in the field and laboratory. Instead, the McPhail trap baited with protein was the most attractive, followed by brewer hydrolysate, protein hydrolysate + pumpkin powder, and pumpkin juice in the attraction ranking. The pumpkin powder alone did not attract the fruit fly. The crude extracts of pumpkin induced behavioral responses (attraction and oviposition) of B. depressa. Some of volatile compounds from pumpkin fruits elicited significant EAG response to female antennae. (R)-(+)-Limonen, Nonyl aldehyde, P-Cymene, Octyl aldehyde, 2-Ethyltoluolen, 3-Ethytoluol, and Cumene showed slight attraction of B. depressa adults. However, no attraction was observed in the field.

Identification of the Trail-Following Pheromone of the Pest Termite Amitermes evuncifer (Isoptera: Termitidae)

Esse Anani Kotoklo [1], David Sillam-dusses[2], Guillaume Ketoh[3], Etienne Semon[4], Alain ROBERT[5], Christian BORDEREAU[6], Isabelle Adole GLITHO[7]

[1]University of Lome, Togo, [2]France, [3]University of Lome, [4]France, [5]France, [6]France, [7]Universite de Lome, Togo

Amitermes evuncifer (Termitidae, Termitinae) is a pest termite in several countries of Africa, damaging crops and buildings. The trail-following pheromone of this termite was isolated from worker sternal glands and identified by GC-MS after solid phase microextraction (SPME). The pheromone is composed of (3Z,6Z,8E)-dodeca-3,6,8-trien-1-ol (dodecatrienol) and neocembrene acting in synergy, neocembrene being 5-10 times more abundant than dodecatrienol. Dodecatrienol alone is able to elicit trail-following in workers, whereas neocembrene alone is inactive. However, the association of both components induces a significantly higher trail-following activity. Multicomponent trail-following pheromones were only known, until now, in the Termitidae Nasutitermitinae, and in the Rhinotermitidae Prorhinotermes.

Prediction of distribution and abundance of ants based on climate change of A1B climate scenario

Tae-Sung Kwon[1], Cheol Min Lee[2]

[1]Korea Forest Research Institute, Republic of Korea, [2]Korea Forest Research Institute, Republic of Korea

Distribution and abundance of ants are highly dependent on temperature. Therefore, the change of ant distribution due to global warming can be predicted using a temperature-based model. In order to develop the model, we surveyed ants at the 366 sampling sites of forests in the whole region of South Korea using pitfall traps from 2006 to 2009. In addition, we compared abundance of ants in the Gwangneung forest between 1993 and 2009 in order to test influence of global warming on local ant community. Of 58 ant species collected, 20 common species which occurred at more than 10% of sampling sites were analyzed on the relationship between abundance and temperature, and 16 species were found to have high relationship. The temperature-dependent species were considered as climate indicators, and their abundance and distribution in 2011, 2020, 2060, and 2090 were estimated on A1B climate scenario. The prediction shows that 11 species will decrease as the globe warms, but 5 species will increase. In the Gwanneung forest, Myrmica kotokui Forel occurred in 1993 but disappeared in 2009. This species is estimated to be most vulnerable to global warming on the model. This species is most abundant in the highlands in South Korea in 2011, but is expected to disappear almost in 2090.

Local change of butterfly species in response to global warming and reforestation

Tae-Sung Kwon[1], Cheol Min Lee[2]

[1]Korea Forest Research Institute, Republic of Korea, [2]Korea Forest Research Institute, Republic of Korea

It is expected that the successful nationwide reforestation and global warming will greatly change the butterfly fauna in South Korea. We compared current data (2002~2007) regarding the abundance and presence of butterfly species at 2 sites in the central portion of the Korean Peninsula with similar data from the late 1950s and early 1970s for the same sites. The expected changes were documented by an abundance change of butterflies at the 2 study sites in the previous study. Using the same data, the most greatly changed species and the change of species presence were analyzed. Population changes of 99 butterfly species which occurred at both sites were significantly correlated between the 2 sites. The greatly increased species included 3 Southern (S) species and one Northern (N) species. However, the species showing great decline included 5 N species and no S species. This change coincided with the expectation of northward movement of butterfly species due to global warming. The current status of the greatly changed species is discussed along with other studies. The binary data (presence/absence) in the present study support the expected changes of butterfly species based on global warming and reforestation. The interactive effect of 2 environmental changes was also recognized, as well as the change of abundance in the previous study.

Locality records of potato tuber moth, *Phthorimaea operculella* (Zeller), distributed in the Korean Peninsula

Min Kwon[1], Ju Il Kim[2], Jeom Soon Kim[3], Young Gyu Lee[4], June Yeol Choi[5]

[1]National Institute of Crop Science, RDA, Republic of Korea, [2]National Institute of Crop Science, RDA, Republic of Korea, [3]National Institute of Crop Science, RDA, Republic of Korea, [4]National Institute of Crop Science, RDA, Republic of Korea, [5]Rural Development Administration, Republic of Korea

Potato tuber moth (PTM), Phthorimaea operculella (Zeller), is a cosmopolitan pest, especially in warm temperature and tropical regions where host plants, mostly belong to family Solanacea, are cultivating. In recent years, the species has been inadvertently occurred in the potato fields of middle areas of Korea. To determine the distribution of PTM, we carried out an extensive survey using sex pheromone traps at 38 sites across the nation during 2009~2011. Delta-typed traps were baited with rubber septa impregnated with commercially available PTM sex pheromone. In each area surveyed, a potato field approximately 0.1~3 ha in size was selected and 2 traps were randomly placed in that field 1 m above ground level. As a result, we confirmed that the range of PTM extended from southern coastal regions to the central regions of the Korean Peninsula. The northern limit of PTM distribution expanded to northern Gyeonggi (Yeoncheon, Gangwha, Gimpo, Paju) and middle Gangwon regions (Goseong, Inje, Pyeongchang) from Gyeongbuk and Chungbuk regions reported first by Choi & Park (1980). Based on these data, we investigated why drastic going northward of PTM happened in Korea. Here is one presumption that a sudden rise in average temperature has occurred during 30 years, from 6.34℃ of 1973 to 7.62℃ of 2007, in the Korean Peninsula.

Phylogenetic diversity of lignocellulosic biomass-degrading bacteria in the digestive tracks of a mole cricket (Gryllotalpa orientalis) and an earthworm (Eisenia fetida) were investigated. Of the 86 different heterotrophic bacteria isolated from the digestive track of E. fetida, 29 bacterial strains in this study were identified as lignocellulosic biomass degraders capable of hydrolyzing carboxymethyl cellulose, xylans, or mannans. Phylogenetic analysis showed that these fibrolytic bacteria were affiliated with the Gram-positive phyla of Firmicutes and Actinobacteria. Similarly, 32 morphologically different exo-symbiotic heterotrophs were selectively isolated from the digestive track of G. orientalis. However, only 13 bacteria exhibited hydrolytic activity towards the aforementiond polysaccharide substrates. These bacterial isolates were evaluated to be phylogenetically classified into the Gram-positive phyla of Actinobacteria and Firmicutes and the Gram-negative phylum of Proteobacteria. Based on these results, it is proposed that similar to the termite digestome, the digestomes of G. orientalis and E. fetida can be also very useful as sources of diverse cellulolytic and hemicellulolytic intestinal bacteria, which are expected to possess novel genes encoding particular glycoside hydrolase (GH) enzymes.

Study of preservation and proliferation of the endangered species (*Argynnis nerippe*) in western islands of South Korea

Bo-Sun Park[1], Yong-Ki Kim[2], Yonungdon Ju[3], Vi Xuan Le[4], Mu-jie Qi[5], Ulziijargal Bayarsaikhan[6], Heejo Lee[7], Min-seon Kim[8], Yang-Seop Bae[9]

[1]University of Incheon, Republic of Korea, [2]University of Incheon, Republic of Korea, [3]University of Incheon, Republic of Korea, [4]University of Incheon, Vietnam, [5]University of Incheon, China, [6]University of Incheon, Mongolla, [7]University of Incheon, Republic of Korea, [8]University of Incheon, Republic of Korea, [9]University of Incheon, Republic of Korea

In Guleopdo, western islands of South Korea, we found an endangered species Argynnis nerippe. Guleopdo has widely grassland for Argynnis nerippe as a habitat, which can provide enough resources for them to live (Kim, Lee & Kwon 2011). In the past, grassland in Guleopdo has been used for feeding livestock, such as cows and black goats. Then, here is changed grassland from peanut farm about 80 years ago. In order to know the differences between Guleopdo and the nearby islands, we compare the fauna of the 7 islands in western of South Korea around the Guleopdo. During June to July, 2011, we visited 7 islands by 4 times field trips. We swept in day time and used light trap in night time. As a result, We found 10 orders, 50 families, 160 species in Guleopdo; 6 orders, 44 families, 141 species in Baegado; 5 orders, 11 families, 13 species, in Sungapdo; 6 orders, 15 families, 19 species in Jido; 8 orders, 19 families, 21 species in Uldo. Comparing with each islands, Baegado has the most approximate result with Guleopodo. The richness index of Guleopdo is 0.6078, and the Baegado is 6.458. The biodiversitiy index Guleopdo is 2.98, Baegado is 3.019. Now Guleopdo can afford to support A. nerippe. But, if natural disaster and ecological succession destroy grassland, the species A. nerippe will disappear in Guleopdo. So making Baegado similar with Guleopdo, we can spread and protect that species better.

Host preference of *Plutella xylostella* (Lepidoptera: Yponomeutidae) to cruciferous vegetables

Eun-jung Han[1], Jae-Pil Choi[2], Min-Ho Lee[3], Jong-ho Park[4], Yong-Ki Kim[5], Seong-Jun Hong[6], Chang-Ki Shim[7], Min-Jeong Kim[8], Hyeong-Jin Jee[9]

[1]NAAS, RDA, Republic of Korea, [2]NAAS, RDA, Republic of Korea, [3]NAAS, RDA, Republic of Korea, [4]NAAS, RDA, Republic of Korea, [5]NAAS, RDA, Republic of Korea, [6]NAAS, RDA, Republic of Korea, [7]NAAS, RDA, Korea, Republic of Korea, [8]NAAS, RDA, Republic of Korea, [9]NAAS, RDA, Republic of Korea

The organic cultivation area has increased rapidly during the last decade in republic of Korea. Despite the outer growth of organic agriculture, management of insect pests relies on organic materials such as insecticidal plant extracts and commercial Bacillus thurigiensis, because there is no enough information about ecological pest control. In this study, we estimated preference of diamond back moth (Plutella xylostella) to 13 cruciferous vegetables in the laboratory and in glasshouse to select trap crops as a component of 'push-pull strategy' for chinese cabbage cultivation. Cruciferous vegetables tested were pak-choi, dacheongchae, two kinds of red cabbages, head lettuce, turnip, rape, kale, green leaf mustard, red leaf mustard, broccoli, red mustard and Chinese cabbage. Results from Y-tube olfactometer studies through comparing orientation of P. xylostella between treatment of each cruciferous crop and blank treatment indicated that P. xylostella was attracted by all of the cruciferous vegetables. However, in the experiment comparing attractiveness of each cruciferous vegetable to Chinese cabbage, rape attracted P. xylostella more than chinese cabbage. Oviposition preference tests conducted in a cage (60cm×60cm×60cm) showed that P. xylostella preferred to lay eggs on turnip, rape, red mustard, green leaf mustard and red leaf mustard compared to chinese cabbage. These results suggest that rape be a promising trap crop for Chinese cabbage cultivation.

The geographical distribution and ecological preference of ixodid ticks in Korea were surveyed at 22 regions from April to September 2011. We collected 15,083 ixodid ticks with 3 genera, 7 species, using dry ice bait trap and flagging. Among them, Genus Haemaphysalis, Ixodes and Amblyomma accounted for 15,035 (99.7%), 47 (0.3%) and 1 (<0.0%). Respectively, Genus Haemaphysalis consisted of 4 species, H. longicornis (92.6%), H. flava (7.1%), H. formosensis and H. hystricis (<0.1%). Genus Ixodes consisted of 2 species, I. nippoenesis (0.2%) and I. persulcatus (0.1%). Genus Amblyomma was only A. testudinarium. H. longicornis was the most highly collected more than 52.2% in the whole region, except Hamyang-gun of 19.0%. And H. flava was collected less than 44.8% in the whole region, except Hamyang-gun of 78.6%. I. nipponensis was infrequently collected in 11 regions, and I. persulcatus was only collected in Pyeongchang-gun. The grassland site was the most highly infested site (42.1%). The collection sites for ticks consisted of coniferous forest, broad-leaved forest, mixed stand forest, grassland, bamboo grove and other sites.

Interaction between herbivores and leaf quality at rural landscape of Southwestern Korea.

Jin Lee[1], Jeong-Seop An[2], Sei-Woong Choi[3]

[1]Mokpo national university, Republic of Korea, [2]Mokpo national university, Republic of Korea, [3]Mokpo National University, Republic of Korea

Insect and plant interaction emerges as consequence of evolution through complex physical, chemical, and environmental factors. The interaction adapts itself in different ways to the changing condition. The present study was aimed at investigating the interaction between herbivore and its food plant qualities. We collected lepidopteran larvae using beating method from May to September at a rural landscape. Two dominant food plants, Eurya japonica and Quercus serrata were chosen and nitrogen, carbon and water content of each plant were measured. We found that temporal change of species richness was related with carbon and nitrogen content (R_{adj}=0.749, $F_{1,10}$=11.044,<0.01). However, the larval populations on these two food plants were not related with plant chemical qualities. In addition we collected weather date such as mean temperature, relative humidity, quantity of solar radiation, mean wind speed, maximum instantaneous wind speed and rainfall. Temporal change of species diversity was only related with the maximum instantaneous wind speed (R_{adj}=0.501, $F_{1,10}$=11.044, <0.01). Consequently, an understanding of the interaction between herbivore and food plant should be based on the interaction of Lepidopteran larvae and leaf qualities of their food plant and its environmental factors.

Distribution and habitat of Korean *Osmia* spp. in apple orchard of Korea

Kyeong Yong Lee[1], Hyung Ju Yoon[2], Sang Beom Lee[3], In Gyun Park[4], Mi Ae Kim[5]

[1]Department of Agricultural Biology, The National Academy of Agricultural Science, RDA, Republic of Korea, [2]Department of Agricultural Biology, The National Academy of Agricultural Science, RDA, Republic of Korea, [3]Department of Agricultural Biology, The National Academy of Agricultural Science, RDA, Republic of Korea, [4]Department of Agricultural Biology, The National Academy of Agricultural Science, RDA, Republic of Korea, [5]National Academy of Agricultural Science, RDA, Republic of Korea

We investigated the distribution and habitat characterization of Korean Osmia spp. in apple orchard of 32 localities during 2005 to 2008. A total of 6,737 Osmia spp. were collected, consisting of six species, which was Osmia cornifrons, O. pedicornis, O. taurus, O. benefica, O. satoi and O. jacoti. The rate of bee nested was 11.7%. Among collected 32 localities, Choongju showed the most collecting rate among other localities, which was 22.4% and 17.5% for Yeongju and 14.9% for Geochang. In case of collected six Osmia spp, O. cornifrons was 60.2%, which was the dominant species and O. pedicornis was 20.4% and O. taurus was 10.8%, respectively. In case of sex ratio, O. cornifrons was 1 : 2.7 and 1 : 5.6 for O. pedicornis and 1 : 2.3 for O. taurus. Osmia spp. was more collected at habitat conditions within apple orchard with plentiful pollens place and abundant water.

The genetic relatedness assay through the nuclear gene analysis in *Vollenhovia emeryi* (Hymenoptera: Myrmicinae)

Haewon Shin[1], Jae Chun Choe[2], Gilsang Jeong[3]

[1]Ewha Womans University, Republic of Korea, [2]Ewha Womans University, Republic of Korea, [3]Ewha Womans University, Republic of Korea

Vollenhovia emeryi ant is distinguished by its wing morphology; short winged (SW) and long winged (LW). Its reproduction shows a bizarre genetic caste system distinct from other social hymenopteran insects. Unfertilized eggs undergo genome duplication and develop into clonal gynes. Fertilized eggs develop either into workers or males. The fate of the fertilized eggs is determined whether maternal genome loss (MGL) takes place after fertilization. Eggs with MGL become haploid males with only paternal half of the genome. Without MGL, the eggs become workers with maternal and paternal half of the genome. In this research, we analysed 5 nuclear genes of SW and LW individual ants. Among them, two genes from an SW male are identical to those of LW, and one gene from the SW male seems a variant of LW. The result indicates that SW males are derived from LW colonies. From the genetic relatedness point of view individuals in the same castes are genetically identical. On the other hand, between workers and two reproductives, the relatedness is asymmetrical and there is even no gene sharing between gynes and males. The conventional genetic relatedness by Hamilton is revised under this condition.

The mitochondrial genetic population structure of the ant species, *Vollenhovia emeryi* (Hymenoptera: Myrmicinae) in Korea

Seung-Yoon Oh[1], Jae Chun Choe[2], Gilsang Jeong[3]

[1]Kunsan National University, Republic of Korea, [2]Ewha Womans University, Republic of Korea, [3]Ewha Womans University, Republic of Korea

The ant species, Vollenhovia emeryi, is distributed in Far East. The species can be divided into two major groups by their wing morphology of reproductives: short-winged and long-winged. A nationwide survey of the species was conducted for analyzing the mitochondrial haplotype diversity and genetic population structure. We collected 91 samples from 40 locations. A total of the 1239 bp partial COI (cytochrome C oxidase 1) region was used for the analyses. We found the total of 21 haplotypes. The mitochondrial haplotypes may correspond to the wing morphology. The genetic population structure examined potential geographic barriers of gene flow such as distance, mountains, rivers and plains which are non-mountain areas to prevent dispersal through mountain range. The result implied that no barriers considered in this study affected differently gene flow. Therefore, the behavioral characteristics of the ant may be the causal constraint of its genetic exchange.

Keywords:*Vollenhovia emeryi, wing morphology, population structure, mt-COI haplotype diversity, gene flow bar*

Anti-allergic effects of venom from honeybees (*Apis mellifera* L.) on production of nitric oxide and cytokines in THP-1 Cell line and ige level and the scratching behavior in NC/Nga mice

Hyun Bae Kang[1], Hae Jin Lee[2], Sang Jin Jeon[3], Sang Kyun Koh[4], Ji-Sook Lee[5], Chi-Young Yun[6]

[1]Daejeon University, Republic of Korea, [2]Daejeon University, Republic of Korea, [3]Daejeon University, Republic of Korea, [4]Daejeon University, Republic of Korea, [5]Wonkwang Health Science University, Republic of Korea, [6]Daejeon University, Republic of Korea

Bee venom (BV), as traditional oriental medicines, has been well known the pain reliever and anti-inflammatory agent for a long time, and shown anti-arthritic and anti-carcinogenic effects. In this study, we investigated the effect of bee venom on the THP-1 cell stimulated by house dust mites (HDMs), which mediate the activation of T cell and monocyte, and induce the elevation of serum IgE levels in atopic dermatitis (AD) patients, for the elucidation of anti-allergic activity. THP-1 cells activated with HDMs were treated with different doses of BV and then the supernatant was analyzed for the production of NO and cytokines using Griess reagent and ELISA, respectively. RNA levels in the THP-1 cells were measured by a reverse transcriptase-polymerase chain reaction. The results indicated that BV suppressed HDMs-induced NO and inducible NO synthesis expression in a dose-dependent manner, and also represented that BV exerted anti-allergic effects by suppressing the transcription of cytokines, such as IL-6, IL-8, IL-13, TNF-α, ICAM-1 and MCP-1. We also examined the dorsal skin administration of BV to NC/Nga mice treated by 2,4-Dinitrochlorobenzene (DNCB) was found to inhibit increase of the ear thickness and the skin lesions. In the evaluation of the scratching behavior, it decreased in 15-20%. The serum IgE production of the mice was significantly inhibited by BV treatment. These results suggest that BV has anti-allergic activities, and thus can be useful in inhibiting the production of some cytokines in AD. Further studies involve the analysis of the individual components of BV and their pharmacological aspects.

Fruit borers such as Grapholita molesta, Grapholita dimorpha and Carposina. sasakii are major pests of plum in Korea. Population densities and seasonal occurrence were monitored using the synthetic sex pheromone trap in Uisung and Gyoungsan, two important plum growing area in Korea. In 2010 and 2011, overwintering adults of G. molesta were caught from mid April with the peak of late April, and then undergone 3 more generations in Gyoungsan. Grapholita dimorpha appeared from late April with 3 peaks afterward until late September. Both Grapholita species occurred a few days later in Uiseong where the latitude is 1? high. There was no difference between the season of C. sasakii between Gyoungsan and Uiseong with the same patterns of 2 or 3 peaks. Population size was in order of G. molesta, G. dimorpha and C. sasakii with 63:16:20 and 47:35:18 in Gyoungsan and 51:18:31 and 46:13:36 in Uiseong, in 2010 and 2011 respectively. There was no difference of catches of Grapholita species in the trap installed inside and outside of the orchards.

Diversity of gamasid mites (Acari: Mesostigmata, Gamasida) in different agroecosystems

Eun Sun Keum[1], Jiwon Kim[2], Chuleui Jung[3]

[1]Andong National University, Republic of Korea, [2]Andong National University, Republic of Korea, [3]Andong National University, Republic of Korea

Gamasid mites are important predators in soil ecosystem including agricultural lands. We compared the gamasid mite diversity in different agricultural systems; pine forest as a natural ecosystem, apple orchards as a perennial crop, potato and Chinese cabbage fields as an annual crop. Diversity and abundance were highest in the pine forest followed by apple orchards and then potato and Chinese cabbage fields. In the pine forest, more species and individuals were collected from the primary forest compared to the secondary forest. In apple orchards, more species were found from the organically managed orchards than from the conventionally managed ones, but the abundance patterns were in reverse. Annual crop system harbors least diversity and abundance of soil gamasid mites indicating that the disturbance and input of organic materials influence the gamasid assemblage. Dominant species were Asca nubs, Parasitidae sp. 2, 3, 4, Gamasholaspis browning, G. communis, Holaspina alstoni, H. dentatus, H. sp. 1, Veigaia ashizuriensis, V. ochraceus, V. tibbetis in the pine forests, Eugamasus fujisanus, Holaspina ochraceus, Leioseius insignis, Uropoda hikkaidoensis, V. ashizuriensis, V. uenoi in the apple orchards, and Leioseius sp. 1 in the annual crops.

Comparison of oribatid mite communities between the pine forest and apple orchards

Ji won Kim[1], Eunsun Keum[2], Chuleui Jung[3]

[1]Andong National University, Republic of Korea, [2]Andong National University, Republic of Korea, [3]Andong National University, Republic of Korea

Community structures of oribatid mites in the pine forest and apple orchards were compared as an example of natural and disturbed habitat of oribatid mites. Diversity and abundance were higher in the pine forest than the apple orchards. In pine forest, primary forest harbored more diversity but less abundance when comparing to the secondary forest. However, the diversity was higher in conventionally managed apple orchards than organically managed ones but the abundance was not different. Common dominant species in pine forest were Cultroribula lata, Ceratozetes japonicas while Epidamaeus khustaiensis, Eremobelba japonica and Eremaeus tenuisetiger were dominant in primary and Oppiella nova, Scheloribates pallidulus were in secondary. In apple orchards, Pergalumna duplicata nipponica, Scheloribates latipes were the common dominant species while Hypochthonius luteus was dominant in organic apple orchard and Pergalumna altera, Scheloribates corpusculum, Punctoribates sphaericus were dominant in conventional orchard. Further study on the functional aspects and association with other soil biotic and abiotic factors are demanding.

Comparison analysis of acoustic signals to *Liriomyza trifolii* (Diptera: Agromizidae) with the EAG signals

Chang Woo Ji[1], Si Woo Lee[2], Yeon Kook Kim[3], Sang-Guei Lee[4]

[1]National Academy of Agricultural Science, Republic of Korea, [2]National Academy of Agricultural Science, Republic of Korea, [3]National Academy of Agricultural Science, Republic of Korea, [4]National Academy of Agricultural Science, Republic of Korea

We investigated an antenna response of Liriomyza trifolii (Diptera: Agromizidae) to acoustic signals by using the EAG (Electroantennogram) technique. Originally, EAG have been used to observation of neural transferring of the olfactory response in antenna of insect. It seems quite probable, because the auditory organ known as Johnston's organ in fly was located in antenna. In this study, we tried to utilize the EAG for comparison the relationship with acoustic signals and antennal response. Pure tone sounds (sine wave), which were varied from 20 to 1,000 Hz according to different sound pressures (50 ~ 100 dB), were exposed to excised head of test specimens. Neural response in antenna was strongly appeared against low level frequency and high level sound pressures. In conclusion, EAG signals would be useful for detecting the antenna response to acoustic signals.

Genetic variation in tendency to diapause in spider mite *Tetranychus puerariicola*

Katsura Ito
Faculty of Agriculture, Japan

12 iso-female lines were established from a population of the adult-diapausing spider mite, Tetranychus puerariicola. The diapause incidences of each line were investigated for 18, 19, and 20°C and LD 10:14 h conditions. There was significant genetic variation in the each temperature conditions. Genetic correlation between temperatures was about 0.7 in either combination.

Life table-based computer simulation of population dynamic of *Spodoptera litura* (F.) fed on groundnut (Arachis hypogaea) leaves under different condition

Shu-Jen Tuan[1], Chung-Chieh Lee[2], Hsin Chi[3]

[1]National Chung Hsing University, Taiwan, [2]National Chung Hsing University, Taiwan, [3]National Chung Hsing University, Taiwan

Spodoptera litura (F.) is the most destructive leaf-defoliating pest of peanuts (Arachis hypogaea) in Taiwan. To accurately simulate the population dynamics of S. litura, life table data, using the age-stage, two-sex life table, were collected at constant temperature 25ºC in the laboratory, and outdoors under field conditions in the spring and fall of 2010. Results showed that there were significant differences in developmental times, survival rate, fecundity, and hatch rate under different conditions. The shortest immature stage occurred in fall (19.2 d), while the longest was in spring (28.4 d). At 25℃, both male and female adults lived longer than adults under field conditions. The mean generation time was the shortest in fall (34.5 d). The preadult survival rates in spring (39.9%) and fall (53.3%) were lower than the rate observed at 25℃ (84.6%). The mean fecundity of S. litura was 3548, 3452, and 3072, at 25℃, in spring, and fall, respectively. The hatch rates were 64.2, 72.2, and 26.0%, respectively. At 25°C, the intrinsic rate of increase (0.1838 d-1), finite rate of increase (1.2017 d-1), and net reproductive rate (963.2 offspring) were the highest among all treatments. Population parameters showed high variability in spring and fall. Because both hatch and survival rates in the field were affected by various unregulated environmental factors, they were lower than those obtained at constant temperature. Our results demonstrate that computer simulation based on life tables collected under both laboratory and field conditions is an important tool for prediction pest emergence.

Multiple generation effects of high temperature on the development and fecundity of *Bemisia tabaci* (Gennadius) (Hemiptera: Aleyrodidae) biotype B

Jian-Ying Guo[1], Lin Cong[2], Fang-Hao Wan[3]

[1]Inst. of Plant Protection, Chinese Academy of Agricultural Sciences, China, [2]Inst. of Plant Protection, Chinese Academy of Agricultural Sciences, China, [3]Inst. of Plant Protection, Chinese Academy of Agricultural Sciences, China

Insects are ectotherms and their ability to resist temperature stress is limited. The immediate effects of sub-lethal heat stress on insects are well documented, but longer-term effects of such stresses are rarely reported. We studied sub-lethal high temperature effects on the survival, development and reproduction of invasive whitefly Bemisia tabaci (Gennadius) (Hemiptera: Aleyrodidae) biotype B over five successive generations. Both temperature and generation significantly affected the fitness of the whitefly. Among the tested temperatures of 27°C, 31°C, 35°C and 37°C (± 1°C), the most favorable for development and reproduction were 27°C and 31°C. At 27°C, survival, development and fecundity were all stable over these five generations. At 31°C, egg hatching rates decreased in the third to fifth generations, female fecundities decreased in the fourth and fifth generations, and female percentage and adult longevity fluctuated among the generations. At 35°C, egg hatching rate and immature survival rate decreased and immature development time increased with generations, female fecundities decreased in the fourth and fifth generations, and female percentage and longevity fluctuated among the generations. Female fecundity at 37°C was less than 10% of that at 27°C or 31°C and the whitefly culture at 37°C lasted for only one generation. The lower threshold of lethal high temperature of B. tabaci biotype B was higher than 37°C, and the whitefly population continued expanding in the five generations at 35°C. The ability of B. tabaci biotype B to survive long-term high temperature stress will play an important role in its population extension under global warming.

Ecological niche of 16 species of bark beetles (Coleoptera: Scolytidae) within *Pinus armandi* of Huoditang located ecosystem station of Tsinling Mountains

Jing Li

Beijing Forestry University, China

Bark beetles, the major pest caused a fatal damage of Pinus armandi of Huoditang Foresty Station in Tsinling Mountains, were investigated on organization level and temporal-spatial niche. The result showed that the bark beetles community was abundant, containing 16 species of them. Dendroctonus armandi, Cryphalus lipingensis, Ips mannsfeldi and I. sexdentatus were the major species. Analyzed by Levins, Shannon-Wiener and Pielou formulas, we concluded that they've appeared to vertical distribution. D. armandi was the pioneer species because of the largest number of individuals and the most broad niche breadth. Besides, Hylastes parallelus and Polygraphus polygraphus occupied within the roots and the base of trunk. Yet some Ips bark beetles were densely distributed in the top of tree trunk and branches, such as Tomicus piniperda and Cryphalus lipingensis. Other bark beetles, Hylastes parallelus, Dermestes sp., Dermestes sp., etc. were distributed with relatively narrow breadth. The statistical data reflects other 7 species had their own spatial and overlap niche within the main trunk. So all these species hold with a dynamic model of competitive equilibrium to coexist by their biological and ecological characteristics.

Efficiency of ten population of *Schizaphis graminum* (Rondani) in transmission of barley yellow dwarf virus-PAV (BYDV-PAV) in Iran

Ali Mirshekar
University of Zabol, Iran

Variation in transmission of ten clones of Shizaphis graminum (Rondani) originating from different region of Iran was evaluated by transmitting an isolate of barley yellow dwarf virus-PAV (BYDV-PAV) for which this species is normally an inefficient vector. After acquiring the virus, aphids of each clone-virus isolate combination were caged on 30 seedling using 3 forth instar nymph per seedling. The inoculated and control plants were assayed by ELISA and assayed visually to determine the rate of transmission and the mean ELISA value for each treatment. A positive correlation was found between the rate of transmission and the mean absorbance value. Aphid clones differed in their efficiency of transmission of virus isolate. On the other hand, any single clone transmitted virus isolate with varying efficiencies. The aphid clone belonging virus isolate origin transmitted virus isolate at highest rate. In general Shahre kord and Shahreza clones of aphids showed highest efficiency of transmission and Delijan and Varamin clones have lowest transmission efficiency between aphid clones.

Photosynthesis and sink activity of cecidomyiid galls in Litsea acuminate leaves

MengYuan Huang[1], Man-Miao Yang[2], Chang-Chang Chen[3], Pei-Ju Chen[4], Yung-Ta Chang[5], Chi-Ming Yang[6]

[1]Academia Sinica, Taiwan, [2]National Chung-Hsing Universityversity, Taiwan, [3]Academia Sinica, Taiwan, [4]National Taiwan Normal University, Taiwan, [5]National Taiwan Normal University, Taiwan, [6]Academia Sinica, Taiwan

Multiple changes in response to gall inducers have been found in host plant tissues. While much attention has been focused on the morphology and anatomy of insects or their induced galls, relatively little work has been done on the photosynthesis. In this study, we used pigments and soluble protein contents, gas exchange, chlorophyll fluorescence, scanning electron microscope and confocal laser scanning microscope to investigate the photosynthetic characteristics of leaf-derived cecidomyiid galls and their leaves. In contrast to the host plant leaves, herbivorous insects altered both chlorophyll biosynthetic and degradation pathways of galls on host plants. The gall tissues had lower solute protein contents than leaves. The gas exchange of gall was not found, and the stomata were also not found on the surface of galls. Furthermore, photosynthetic performance was also evaluated by measuring chlorophyll fluorescence. When compared chlorophyll fluorescence in leaves and gall, fluorescence intensity of gall tissues was lower than that of leaves. Based on our survey, we suggest that the leaf-derived cecidomyiid galls are novel sinks in Litsea acuminata leaves.

The Khinjuk psylla , Agonoscena bimaculata Mathur was reported as a pest of the Pistacia khinjuk stocks in Khajoei mountainous area in Sirjan , siuthern part of Iran . In this research ,in fluence of temperature on population growth parameters of A. bimaculata on Khinjuk trees , P. khinjuk and cuptivated pistacia in laboratory conditions at 25 , 27.5 and 32 Cº , 55±5 % RH and photoperiod of 16:8 (L:D) hours.The lowest developmental time for psyllid eggs and nymphs was obtained at 32 ºC, 4.4 and 11.1 days respectively . The in fluence of host plants , e.g. P . vera and P. khinjuk on fecundity of this psyllid were checked . The results showed that egg laying of A. bimaculata under controlled condition is larger on P.khinjuk although the differences were not significant.

Insects associated with plantations of some exotic and indigeneous tree species in Ondo state

Sunday Adeniyi Adeduntan[1], Johnson Adeyinka Olusola[2], Adeola Razaq Jimoh[3]

[1]The Federal University of Technology, Akure, Nigeria, [2]The Federal University of Technology, Akure Nigeria, Nigeria, [3]The Polytechnic IbadDepartment an, Saki campus., Nigeria

The study was carried out to examine the effect of plantation of different tree species on Arthropod diversity and abundance. Three plantations comprising Nauclea diderichii, Gmelina arborea and Tectona grandis within Ondo state were selected for the study. Sample plots of 50 m x 50 m were demarcated in each of the selected sites. Insects sampling and identification was carried out using sweep nets. Soil samples were also collected from each of the selected plots at 0-10cm depth and were carried to laboratory for mesofauna isolation and identification. A total of 43 insects were collected and identified, 17 insects from the 15 years Nauclea plantation, 14 from the 9 years and 12 individuals from the 5 years plantation. A mean abundance of 44 individuals of mesofauna were also encountered, 20 from the G. arborea plantation, 5 from the T. grandis plantation, and 19 from N. diderichii plantation. Shannon Weiner diversity (H') index, for the three age series 1.67, 1.63 and 1.62 for the 15, 9 and 5 years old plantation respectively. While (H') index for the G.arborea and T. grandis plantations were 1.63 and 1.68 respectively. There were significant differences in the mean mesofauna abundance ($P \leq 0.05$) from the samples obtained from different plantation. Also there was no significant ($P \geq 0.05$) difference in the insect species diversity and abundance in all the sites that was studied.

Change of ant species composition in urban parks over time

Sang-Hyun Park[1], Shingo Hosoishi[2], Kazuo Ogata[3]

[1]Kyushu University, Japan, [2]Kyushu University, Japan, [3]Kyushu University, Japan

To compare the change of ant faunas in urban parks over time, we surveyed two parks in Fukuoka City, Japan: Momochi Chuou Kouen Park (MCP) and Minami Kouen Park (MKP), both of which were studied in 1998. The survey was conducted in 2012 using 30 min. time unit sampling with 8 replicates. This sampling method is exactly the same as the one executed in 1998. In MCP, 16 species were collected and estimated species number was 17.63 to 21.47 by Jack- Kinfe method. Compared with the data of 14 years old, the collected species number and estimated species number were almost same (17 spp. with 17.60 to 19.90 spp. in 1998). However, 4 species (Ochetellus glaber, Formica japonica, Nylanderia flavipes, Pyramica membranifera) were not found in 2012 and 3 species Temnothorax spinosior, T. congruus, Monomorium intrudens were newly recorded. This could be a turnover of species. MCP has a simple environment with open space and peripheral artificial vegetation managed regularly. The strong human disturbance may cause the extinction of local population and immigration of ant species. On the other hand, the MKP result showed 19 collected species (20 spp. in 1998) with 24.68 to 27.32 estimated species (23.50 to 27.00 spp. in 1998), where 6 species were not collected this time and 3 species were newly recorded. However, the species change in MKP cannot be confirmed, because the sampled species were too low comparing with estimated species number.

Twig-nesting ant diversity in lowland forests of Cambodia

Shingo Hosoishi[1], Sang-Hyun Park[2], Kazuo Ogata[3]

[1]Kyushu University, Japan, [2]Kyushu University, Japan, [3]Kyushu University, Japan

Twigs are one of the important resources as nesting site for ants, but there has been poorly investigated in tropical Asia. We surveyed two lowland forests (Kampong Chnang, KC and Kampong Thom, KT) in Cambodia, both of which were dominated by evergreen tree species with deciduous tree such as Dipterocarpus spp. Samplings were conducted by collecting dead twigs on trees found within a radius of ca 2 m at each sampling point, and those on the ground found within a 1 m x 1 m quadrate. Each sampling was replicated 8 times in December 2011. In total, 24 species were collected: 12 species were collected in KC, 15 in KT. Three species, Crematogaster ferrarii (17% all colonies caught), Monomorium pharaonis (17%), Tapinoma melanocephalum (13%) were dominant in KC, whereas only one species, Philidris sp. (32%) was dominant in KT. The number of singleton species was higher in KT (12 spp.) than in KC (6 spp.). Some invasive species such as Tapinoma melanocephalum and Monomorium pharaonis were frequently collected in KC. Species of Crematogaster (Colobocrema), and Vombisidris were rare and found in KT. The total species richness of twig-nesting ants, including both arboreal and ground samples in the two forests, is roughly estimated to be around 50 species (Jackknife 2). KC is a community forest and the floors are poorly covered by vegetation, whereas KT is a regrowth forest with abundant shrubs and weeds.

Seasonal abundance of horse fly (Diptera: Tabanidae) in Western Anatolia

Ferhat Altunsoy[1], Ali Yavuz Kılıc[2], Cenk Onsoy[3]

[1]Anadolu University, Turkey, [2]Anadolu University, Turkey, [3]Anadolu University, Turkey

Adult horse flies take blood meals from many mammals including human, so they have known as serious pests wherever they occur and also are known vectors of numerous disease agents. Seasonal abundance of Tabanidae species was monitored during from May to September of 2005, 2006 and 2007 years, in Western Anatolia, Turkey. Totally, 7293 specimens from 52 species belonging to nine genera were collected and identified. Seasonal activities of ten most abundant species, Dasyrhamphis umbrinus, Haematopota subcylindrica, Philipomyia aprica, Tabanus bifarius, Tabanus bromius, Tabanus lunatus, Tabanus portschinskii, Tabanus quatuornotatus, Tabanus rupium and Tabanus unifasciatus were analyzed. D. umbrinus, T. bifarius, T. quatuornotatus, T. unifasciatus reached their peak of abundance in June and others species reached their peak of abundance at July. The longest flight period from first week of May to mid-September was determined for the species Haematopota subcylindrica and Tabanus bromius. Moreover, Haematopota subcylindrica was the most abundant with 23.86% and followed by Tabanus bromius with 20.65%. The population peak of species, and also vector potential, for each year can be affected from climatic conditions. Nevertheless, results suggest that the time between from the mid-June to the third week of July can be considered as the potentially higher-risk period of mechanical transmission of pathogens by tabanids for the study area.

Detection of extra host plants for some agricultural insect pests in Sudan

Abdalla Abdelrahim Satti

Environment and Natural Resources Research Institute, Sudan

Numerous phytophagous insects were reported to attack variable host plants (cultivated and wild) since earlier times in Sudan. But, lacking of regular inventories and updates pertained to such plant-insect interactions has led to conceal the real situation, which represented by the appearance of new pests and/or new hosts. Therefore, a part from the findings obtained as a result of sporadic field surveys carried out during the last few years, was the discovery of new hosts for some known agricultural pests in the country. Hence, an attempt was made in this paper to lists such new host plants for seven important pest species. These pests included Bemisia tabaci (Genn.), Aphis nerii Boy., Liriomyza spp., Urentius hystricellus (Richter), Urentius euonymus Distant, Galeatus scrophicus Saunders and Pachnoda interrupta Oliver. More than twenty new records were listed, included 2, 2, 5, 1, 2, 6 and 3 hosts for the previous pests, respectively. However, the accelerated trade movements (nationally and internationally), besides the modern trends in agricultural systems seem to contribute in distribution of new pest and plant species and to impact the natural ecological habitats which ultimately interfere with insect-plant relationships. Consequently, the paper emphasizes the importance of continuing careful studies on these aspects so as to revise the older information and to cope up with any possible future changes.

Utilization of *Anthophora plumipes* (Hymenoptera, Apidae) for pollinating various flowering plants inside the closed conditions

Radha Devkota Adhikari[1], Ryoichi Miyanaga[2]

[1]*Shimane University, Japan,* [2]*Shimane University, Japan*

Anthophora plumipes is a vernal univoltine solitary bee, which is known to be a good pollinator of some plants. To further demonstrate its utilization under closed conditions, foraging and nesting activities were examined by rearing this bee in a greenhouse at Matsue, Shimane Prefecture, Japan (35º29'N, elevation 170 m). Major floral resources provided for foraging were Phacelia tanacetifolia, Borago officinalis, Centaurea cyanus and Solanum lycopersicum. Bees were attracted to artificially made soil blocks quickly after releasing into the greenhouse. Male bees also started chasing females within 12 hours of release. Bees started foraging before 6:00 in the morning and continued until 19:00 even at a low temperature of 9.5ºC to a high of 36.4ºC, showing a high stability over a wide range of temperature. Bees started collecting pollen after 4 days of liberation. The way of collecting pollen was different among the flower types. One female bee made 1-3 nests of single series and/or multi-series type(s). Single series nests had 1-4 cells, and there were 4-8 cells in multi-series nests. In a nest, initial cells were nearly horizontal, followed by brood cells falling downwards. A good brood production (5.13 per female), long active period (more than 35 days) and higher survival rate (at least 75%) of this bee showed high adaptability for foraging and nesting in the closed condition. Their foraging behavior can be judged to be highly efficient, thus can be used as a pollinator of various crops inside the greenhouse in poor facilities.

Origins of virulence: Genetic mechanisms of virulence inheretance in soybean aphid (*Aphis glycines*) biotypes.

Jacob Wenger[1], Andrew Michel[2]

[1]The Ohio State University - OARDC, U.S.A., [2]The Ohio State University - OARDC, U.S.A.

An invasive species, the soybean aphid (Aphis glycines) was introduced to North America in 2000 and quickly established itself as the premier insect pest of soybean on the continent. Host plant resistant (HPR) soybean was bred shortly after the invasion to provide plant based resistance against the aphid, with plant defense stemming from the Rag1 (Resistance to Aphis glycines) gene. While Rag1 soybean was initially effective, an aphid biotype virulent to the plants was discovered prior to commercial utilization. The Rag1 virulent biotype is referred to as biotype 2, while aphids remaining susceptible to the effect of Rag1 are called biotype 1. Using 20 single nucleotide polymorphism markers we compared genetic diversity and distance between concurrently collected and geographically identical populations of biotype 1 and 2 soybean aphid. Populations were collected over a micro and macro-geographic scale across northern Ohio, USA. Preliminary results indicate geographic distance between populations to be more explanatory of genetic relatedness than biotype affiliation, suggesting virulence is controlled through phenotypic plasticity rather than through specific gene inheritance. A plastic virulence phenotype has considerable implications for the implementation of HPR soybean in industrial agricultural systems, and may render the management of aphid virulence more difficult.

Information theory and insect ecology: Read before you apply

Pavel Drozd[1], Ales Dolny[2], Petr Kocarek[3]
[1]University of Ostrava, Czech Republic, [2]University of Ostrava, Czech Republic, [3]University of Ostrava, Czech Republic

Despite various studies emphasizing problems with the interpretation of diversity indices, these indices are being increasingly applied. Probably because of the high species richness of insects, diversity indices are still very popular in entomology. Here, we briefly review diversity indices with emphasis on the Shannon?Wiener index, which is the most popular index and which is based on information entropy measurement. We indicate that the importance of the diversity indices is frequently overestimated and that the indices are often calculated without reasonable interpretation. Detailed analysis of published papers shows that although modern numerical ecology and insect ecology abandoned this trend during the last decade, diversity indices are increasingly used in applied ecological sciences (forestry entomology, agriculture entomology, etc.) We urge that researchers, and especially those working in areas concerned with economic impact, not calculate diversity indices without fully understanding their limitations.

Faunistic data and global warming: Misleading approach or helpful information?

Pavel Drozd[1], Ales Dolny[2], Petr Kocarek[3]

[1]University of Ostrava, Czech Republic, [2]University of Ostrava, Czech Republic, [3]University of Ostrava, Czech Republic

Various authors have recently provided evidence of global warming based on historical data of species distribution and abundance. This approach can be problematic for several reasons. First, causality is unclear. Without experimental design, relationships between climate change and the distribution and abundance of species must be interpreted with great caution. Second, trends in abundance or distribution can be artifacts of inappropriate methodology and especially of unequal sampling effort, which is a major difficulty when faunistic data are analyzed. Here, we use two model insect species as examples of vulnerable organisms with varying trends in population parameters during last years ("relative to climate change"). We demonstrate how unequal sampling effort affects the trends, and we propose some methods for reducing the effect of unequal sampling effort and to thereby obtain more useful outcomes. This study was funded by Institute of Environmental Technologies project, reg. no. CZ.1.05/2.1.00/03.0100, supported by the Research and Development for Innovations Operational Programme and CZ.1.07/2.2.00/28.0149.

Study of wintering stock of cabbage flies

Bekzod Murodov
Surkhandaryo State University, Uzbekistan

To study the over wintering stock of cabbage flies in the autumn after harvesting cabbage, conducted stratified analyzes of the soil. The size of soil samples was 25-25-30 cm in the laboratory the collected puparia were separated by type, in the spring and summer cabbage flies. Puparium washed in water and after drying weighed on torsion scales. Analysis of the weight characteristics puparia of cabbage flies showed that the spring cabbage fly puparia formed in the range of OT3-25 mg/instance. Most of the puparia refers to the weight category of 11-15 mg /instance. Formed a flying cabbage root fly pupae in the range ot5-30 mg /instance, with most of the puparia belongs to the weight category of 11 to 25 mg /instance. Found that the varietal characteristics of cabbage plants can significantly affect the weight of puparia. Analysis of the characteristics of puparia weight spring and summer cabbage flies in different soil horizons showed that the greater weight of puparia, the deeper in the soil they are located. Found that the greater weight of puparia, the greater the likelihood of departure from a female pests, and vice versa, from lightweight puparia, usually predominantly male. Observations of the flight dynamics of cabbage flies in the laboratory showed that at the beginning of summer in the pest population is dominated by males, in the future there was almost certain departure of females.

Foraging cycle of Asiatic honeybee *Apis cerana* in relation to qualitative and quantitative variations in floral rewards of some plants

Dharm Pal Abrol[1], Muniswamyreddy Shankar Reddy[2]

[1]Faculty of Agriculture, Chatha Jammu ? 180009, Jammu & Kashmir, India, [2]Bangalore University, JNANA BHARATHI, BANGALORE, India

Studies were conducted to determine the foraging behaviour of honeybee Apis cerana in relation to variation in nectar characteristics in nectar yield plants viz. Moringa oleifera, Millettia pequensis, Pongamia pinnata and Mangifera indica. All the four plants yielded nectar continuously throughout the day (06:00 to 18.00 hrs). Significant variations occurred in the nectar production pattern of all these plants with peak periods during late morning and noon hours. The nectar production ranged between 0.039+ 0.0042 µl and 0.036+ 0.0042 µl respectively. Similarly, nectar sugar concentration varied significantly between 17.35+ 0.41 and 61.40+ 1.49%. Variations in nectar volume and concentration were found to be significantly influenced by changes in ambient temperature and humidity. Bee visitation was significantly correlated with nectar sugar concentration and nectar secretation pattern. Interestingly, foragers collecting nectar were more predominant during afternoon whereas pollen collectors outnumbered during early morning hours. The rates of foraging and visitation activities of honeybees species indicated the total absence of inter-species competition which is an important attribute for existence of all honeybee species under particular set of conditions The present paper attempts to gain insight into different behavioral pattern of honeybee Apis cerana in relation to floral rewards of flowers and their pattern of presentation in relation to ecological conditions.

Pyrosequencing reveals dominance of *Arsenophonus, Buchnera*, and *Wolbachia* in bacterial communities of an invasive aphid

Raman Bansal[1], Andy Michel[2]

[1]*The Ohio State University, U.S.A.*, [2]*The Ohio State University, U.S.A.*

The soybean aphid (Aphis glycines), a serious pest of soybean, has successfully invaded and adapted into North America, where it was introduced from Asia around year 2000. To understand the potential role of bacterial symbionts in the invasive success of A. glycines, we performed a comprehensive survey of bacteria in A. glycines using 16S rDNA pyrosequencing. Our results suggested that Arsenophonus, Buchnera, and Wolbachia were the major bacteria associated with A. glycines. A few minor genera (relative abundance between 0.1-1.0%) such as Pantoea, Bacillus, Brevundimonas, Lysobacter and Acinetobacter were also identified from pyrosequencing data. Comparison of bacterial communities associated with field-collected (FC) and laboratory-reared (LR) A. glycines samples revealed significant differences in their structure as well as composition. We identified 18 operational taxonomical units (OTUs) that resulted in differentiation of bacterial communities of FC and LR A. glycines. Selection pressures from natural enemies and environmental conditions on field A. glycines were suggested as factors behind differential bacterial communities observed in FC and LR samples. Finally, we discussed the potential roles of facultative symbionts in A. glycines in the light of aphid biology and insect-bacteria symbiotic systems.

Age-stage, two-sex life table of *Brontispa longissima* (Gestro) (Coleoptera: Hispidae) feeding on four palm plant varieties

Tao Jin[1], Yu-ying Lin[2], Qi-an Jin[3], Hai-bo Wen[4], Zheng-qiang Peng[5]

[1]Environment and Plant Protection Institute, China, [2]Environment and Plant Protection Institute, China, [3]Environment and Plant Protection Institute, China, [4]Environment and Plant Protection Institute, China, [5]Environment and Plant Protection Institute, China

The coconut leaf beetle, Brontispa longissima (Gestro) (Coleoptera: Hispidae), is a leaf-feeding beetles native in southeast Asia and the Pacific, and the beetle is a high risk pest of economic importance in South China. Here, the life history of Brontispa longissima (Gestro) (Coleoptera: Hispidae), reared on leaves of coconut (Cocos nucifera Linn.), royal palm (Roystonea regia), bottle palm (Hyophore lagenicaulis) and fishtail palm (Caryota ochlandra Hance) was analyzed using age-stage, two-sex life table under laboratory conditions. Means and standard errors of population growth parameters were calculated using the jackknife method. Moreover, survival rate and fecundity data was applied to project the coconut leaf beetle population in revealing the different stage structure of populations. The intrinsic rates of increase reared on C. nucifera, R. regia, H. lagenicaulis, and C. ochlandra were 0.032, 0.031, 0.019 and 0.044 day, respectively. The B. longissima reared on C. nucifera achieved the highest net reproduction rate at 114.547 offspring pre female. The mean times of B. longissima ranged from 93.178 day(reared on C. ochlandrai) to 161.516 day (reared on H. lagenicaulis). Population projections showed that populations of B. longissima were able to grow considerably faster on C. ochlandra than on the other three host plants. Our results demonstrate that we can accurately describe the survival, development, and fecundity of B. longissima reared on different host plants using the age-stage, two-sex life table. We recommend the age-stage, two-sex life table be used in insect demographic studies.

Two-sex life table analysis of population characteristics of Cadra cautella Walker (Lepidoptera: Pyralidae) on dry and semi-dry date palm varieties of Iran

Nouraddin Profshayesteh Shayesteh
Islamic Azad University, Mahabad Branch, Iran

Life table of almond moth, Cadra cautella Walker (Lepidoptera: Pyralidae) was studied on four main dry and semi-dry date palm varieties (Deyri, Zahedi, Piarom, and Rabbi) of Iran under laboratory condition. Data were analyzed based on the age-stage, two-sex life table theory. Duration of total preadult stages was 42.54, 45.79, 51.48 and 50.41 days on Deyri, Zahedi, Piarom, and Rabbi, respectively. The highest female fecundity of C. cautella on date palm varieties was 245.29 eggs on Zahedi. The intrinsic rate of increase (r) on different varieties of date palm ranged from 0.070 d-1 (on Piarom) to 0.106 d-1 (on Deyri). The highest net reproductive rate (R0) was on Deyri (97.13 offspring) and the lowest value of this parameter was on Rabbi variety (42.16). Our results showed, the highest r, the largest fecundity and the shortest generation time of C. cautella were observed on Deyri variety. Among date palm varieties, Deyri variety is preferred by C. cautella than other varieties.

Seasonal monitoring of the major okra foliage pests and their associated predators complex at El-Gorair Scheme in Merowe Locality, Northern Sudan

Nazar Abdalla Ahmed Bilal[1], Abdalla Abdelrahim Satti[2]

[1]Sudan Academy of Science (SAS), Sudan, [2]Sudan Academy of Science (SAS), Sudan

Okra [Abelmoschus esculentus (L.) Moench] is one of the important vegetable crops in Northern Sudan and many other parts of the country as well. The crop is subjected to great annual losses due to several economic pests like the cotton whitefly (Bemisia tabaci) and cotton aphid (Aphis gossypii). Besides their debilitating effect as a result of sucking plant nutrients, these pests are also known to transmit serious viral diseases to the crop. Although, insecticide application is the sole measure of control practiced in many areas, it is not widely used in this region. Therefore, it was aimed by this research to monitor the occurrence of pests and predators complex associated with okra foliage at El-Gorair scheme in Northern Sudan, as a step forward to evaluate the potential natural pest control in that area. Hence, the prevalent pests and predators were surveyed on okra fields, and their seasonal trends were studied. More than ten predatory species including members of coccinellids, chrysopids, syrphids, mantids and spiders were detected at variable levels attacking mainly B. tabaci and A. gossypii besides other soft insects. Chrisopids and spiders were the dominant predators in autumn and summer seasons, whereas syrphids, chrysopids and some coccinellid species were the abundant groups during winter. However, among the recorded species Chrysoperla carnea seemed to be the most important one in okra crop all the year round. Such rich fauna of natural enemies should be emphasized to encourage ecological control of vegetable pests and to minimize the need for chemical control.

Faunestic survey on the pests of poplar trees species and their distribution

Abbas Hosseinzadeh[1], Zahra Hashemi Khabir[2], Negar Alioghli[3], Nouraddin Shayesteh[4]

[1]Mahabad Branch, Islamic Azad University, Mahabad, Iran, [2]Agricultural and Natural Resources Research Center of West-Azerbaijan province, Iran, [3]Plant Pests and Diseases Research Laboratory of East-Azerbaijan Province, Sarab, Iran, [4]Mahabad Branch, Islamic Azad University, Mahabad, Iran

Area increase of poplar plantations prepares suitable locations for pests' activity. Recognizing the poplar fauna is the first factor in the current study and is useful in integrated pest management. This survey was carried out from 2008 to 2011, in the plantations and nurseries (with the native and exotic poplar species and clones) of West Azerbaijan. The poplar pests were collected by installing light trap, using Steiner trap, sweeping net, direct capture, hand picking, net clothes around infested tree trunks, and rearing larvae of some pests in laboratory, on Populus species such as: Populus nigra, P. deltoides, P. alba, and P. euramericana. At last, 19 species were collected and identified which were as follows: Amorpha populi L., Lymanteria dispar L., Gypsonoma aceriana Froel. Polyphylla olivieri Castelnau, Paranthrene tabaniformis Rott., Chaitophorus populeti Panzer., Cerura vinula L., Pemphigus borealis Tulgren, Pemphigus spirothecae Pass., Melanophila picta Pall., Monosteria unicostata Muls and Rey, Phloemyzus passerini Sign., Melasoma populi L., Capnodis miliaris klug., Nycteola asiatica L., Lithocolletis populifoliella Tr., Salicicola kermanensis Lndgr., Empoasca decedens Paoli, and Chaitophorus leucomales Koch. All of these pests have been distributed in the entire poplar plantation in West-Azerbaijan province, but the highest species richness was recorded in Uremia (with Mediterranean climate) where 26 Populus clones were recorded. The most important point is that the role of poplar clones and climate of regions should not be ignored in distribution of

Distribution of green oak moth, *Tortrix viridana* L. (Lepidoptera: Tortricidae)

Abbas Hosseinzadeh[1], Zahra Hashemi Khabir[2], Negar Alioghli[3], Nouraddin Shayesteh[4]

[1]Mahabad Branch, Islamic Azad University, Mahabad, Iran, [2]Agricultural and Natural Resources Research Center of West-Azerbaijan province, Iran, [3]Plant Pests and Diseases Research Laboratory of East-Azerbaijan Province, Sarab, Iran, [4]Mahabad Branch, Islamic Azad University, Mahabad, Iran

To determine the rate of the infestation of T. viridana in Ghabre-Hossein, Pardanan, Mirabad, Rabat, Banokhalaf, Ghoulak, Dare-ghabr and Khezerabad regions in 2011, random sampling was performed out of 40 trees of various Quercus genus per region. Four branches (50-cm long) from four cardinal directions were cut off as units of sampling for survey on green oak moth larvae and after counting, the larvae were transferred to the laboratory. Larvae of the last instars were separated based on their host oak species and were reared till their entrance to pupa stage. The weight of four-day-old female pupae was measured. Also, the distribution of the pest was determined through installation of five pheromone traps in different regions. Results showed that the trapped adult moths indicated the existence and distribution of this pest in the regions like Ghabre-Hossein, Pardanan, Mirabad and Ghoulak. But, T. viridana was not seen in Rabat, Dare-ghabr, and Banokhalaf regions (more than 1300 meter higher than free sea level with the cold climate). The highest and the lowest rates of infestation in the regions with severe infestation were recorded on Q. infectoria and Q. libani, respectively (df= 2; P<0.01). The collected pupae on Q. infectoria were the heaviest (df= 2; P<0.05). Also, among the infested areas, Pardanan and Khezerabad with 81% and 54%, respectively, were identified as the most and the least infested regions.

Introduction: Separation of light from darkness

Gunther Pass
University Vienna, Austria

About 15 years ago molecular data began to shake up classical ideas on the phylogenetic relationships of major arthropod subtaxa. One of the greatest controversies it has provoked concerns the origin of insects. While for a long time a close relationship between insects and myriapods was the common tenet, the new data points to a close relationship of insects with crustaceans, or to put it more succinctly, the insects are probably a terrestrial subset of crustaceans. Out of these fertile controversies a series of exciting phylogenetic research has sprouted. Several studies have shown that not only the traditional hypotheses on the origin of Hexapoda, but also their monophyletic status must be questioned. Further dispute refers to the earliest branches of the hexapod tree and a plethora of competing hypotheses have been published so far. As a consequence the ancestral phylogeny of hexapods became a case topic to study the problem of deep nodes which are extremely difficult to resolve. After years of intensive attempts to clarify the conflicting hypotheses it is now time for a "separation of light from the darkness" by critical discussion of all available data. The organizers of the symposium have attempted to bring together the leading experts from all fields dealing with the origin and early splits of hexapods. We can expect a comprehensive update of all relevant results to this topic and look forward to many enlightening discussions.

Phylogenomic data support Remipedia as closest relative to Hexapoda

Bjoern von Reumont[1], Emiliano Dell´Ampio[2], Karen Meusemann[3], Gunther Pass[4], Bernhard Misof[5]

[1]Zoologisches Forschungsmuseum Alexander Koenig, Germany, [2]University Vienna, Austria, Austria, [3]Zoologisches Forschungsmuseum Alexander Koenig, Germany, [4]University Vienna, Austria, Austria, [5]Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany

Remipedes are a small and enigmatic group of crustaceans, first described only 30 years ago. The stygiobiontic species of this group dwell in remote underwater cave habitats, so called anchialine caves. New analyses of both morphological and molecular data have recently suggested a close relationship between Remipedia and Hexapoda instead of the former hypotheses that remipedes represent a rather basal split within crustaceans. Thus, remipedes may be pivotal for understanding the evolutionary history of both crustaceans and hexapods. However, to test this hypothesis using new data and new types of analytical approaches from the field of NGS (Next Generation Sequencing) data is important. The most recent phylogenomic analysis of pancrustaceans includes all crustacean species for which EST data are available (46 species), and the largest alignment encompasses 866,479 amino acid positions and 1,886 genes. A series of phylogenomic analyses was performed to evaluate pancrustacean relationships. This included a significantly improved quality of the data for predicting putative orthologous genes and for generating data subsets by matrix reduction procedures, thereby improving the signal to noise ratio in the data. The results demonstrate that the different ways to compile an initial data set of core orthologs and the selection of data subsets by matrix reduction may have marked effects on the reconstructed phylogenetic trees. The inferred phylogenies strongly support Pancrustacea with Remipedia as the sister group to Hexapoda.

Origin and early splits in hexapods: A multidisciplinary approach within the international initiative 1000 Insect Transcriptome Evolution (1KITE)

Daniela Bartel[1], Alexander Blanke[2], Alexander Boehm[3], Makiko Fukui[4], Ryuichiro Machida[5], Karen Meusemann[6], Bernhard Misof[7], Yasutaka Nakagaki[8], Guenther Pass[9], Malte Petersen[10]

[1]University of Vienna, Austria, [2]Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany, [3]University of Vienna, Austria, [4]Graduate School of Science and Engineering, Ehime University, Japan, [5]University of Tsukuba, Sudadaira Montain Research Center, Japan, [6]Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany, [7]Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany, [8]University of Tsukuba, Sudadaira Montain Research Center, Japan, [9]University of Vienna, Austria, [10]Zoologisches Forschungsmuseum Alexander Koenig, Bonn, Germany

Starting about 400 million years ago, the evolution of hexapods is the most impressive success story in the animal kingdom in terms of species richness, diversification and adaptive radiation. While morphological diversity is generally high among the main groups of insects, disparity is highest when comparing entognathous groups with ectognathous lineages. Disparity is likewise high among crustacean subgroups discussed as the potential sister group of Hexapoda. These factors impede the reconstruction of the early splits and consequently of the early evolution of hexapods. Five primarily wingless groups are traditionally subsumed in an assemblage denominated "apterygotes" or 'basal hexapods': Collembola, Protura, Diplura, Archaeognatha, and Zygentoma. In the era of phylogenomics, basal hexapods are prone to be highly underrepresented. Embedded into the recently started 1KITE project which aims to sequence and analyze 1000 insect transcriptoms, working groups of 3 universities (Austria, Germany, and Japan) focus on the relationships and evolution of primarily wingless insects. With about 100 taxa final aim of this project is to analyze the largest taxon sampling concerning the basal hexapod lineages. Phylogenetic questions to be tested encompass: (i) monophyly of Hexapoda and Entognatha, (ii) sister group relationships among the entognathous groups (Collembola, Protura, Diplura) (iii) the sister group of the Hexapoda, and (iv) the phylogenetic position of the living fossil Tricholepidion gertschi. We will analyze not only molecular data sets but also investigate the reliability of these results with new data from developmental, embryological and morphological studies. First results will be presented along with focus, aims and workflow.

Contact toxicity of three formulations from lambda- cyhalothrin against German cockroach, *Blattella germanica* (L.) (Blattaria: Blattellidae)

Gholamhossein Moravvej[1], Aida Saboor Sadeghzadeh[2]

[1]Ferdowsi University of Mashhad, Iran, [2]Ferdowsi University of Mashhad, Iran

The German cockroach, Blattella germanica (L.) is a major household and public health pest worldwide. Current control strategies rely heavily upon various formulations of insecticides. In the present study, contact toxicity of three lambda-cyhalothrin formulations, emulsifiable concentrate (ICON 5 EC®), capsule suspension (DEMAND 10 CS®) and wettable powder (ICON 10 WP®) were tested against 5 to 7-day-old adults of the German cockroach exposed for 1 h. Experiments were conducted at 27±2 °C and 60±10% R.H with a photoperiod of 12:12 h (L:D). The results indicated that mortality of adults increased with increasing insecticide concentration. Males were more susceptible to all formulations than females. The most potent formulation was WP with the LC50 values of 9.87 and 12.24 mg.ai/㎡ against males and females, respectively. The formulation of CS attained the LC50 values of 11.02 and 13.42 mg.ai/㎡ and that of EC attained the values of 12.30 and 15.01 mg.ai/㎡ against males and females, respectively. The results demonstrated that the formulations of WP and CS had high activity against the German cockroach.

Natural enemies of *Bemisia tabaci* on cabbage plants in Qassim, Saudi Arabia

Mohammad Abdulaziz Aldeghairi[1], Nagdy F. Abdel-Baky[2]

[1]Qassim University, Saudi Arabia, [2]Qassim University, Saudi Arabia

Cabbage (Brassica oleracea Linn.) is considered one of the most important vegetable crops in Saudi Arabia. Cabbage agro-ecosystem formed a special ecological niche for a lot of insects, of which the sweetpotato whitefly (Bemisia tabaci, Genn.) is considered a destructive and a key pest of cabbage at Qassim region, KSA. There are three groups of natural enemies found associated with B. tabaci in cabbage. Predatory insects such as Chrysoperla carnea Stephens, Macrolophus caliginosus Wagner (Miridae: Hemiptera), Orius spp. (Anthocoridae: Hemipetra) and Coccinella undecimpunctata L. (Coccinellidae: Coleoptera) which attack B. tabaci immatures in cabbage fields. Chrysoperla carnea was the most abundant and efficient predatory insect species under field conditions, followed by M. caliginosus and Orius spp. compared with C. undecimpunctata. Only, Eretmocerus mundus Mercet (Aphelinidae: Hymenoptera) a parasitoid of B. tabaci was also observed at cabbage fields. This parasitoid had a higher population density and great impact in reducing B. tabaci population under field conditions. Moreover, an entomopathogenic fungi Cladosporium, was also observed infecting nymphs and adults in the field. Natural incidence of Cladosporium spp. was very high and caused a significant natural mortality among B. tabaci life stages. Despite the diversity of insect natural enemies and their population abundance, their effectiveness is still very low in the field. This may be due to the mutual inference effects among natural enemies, or may be the efficiency of insect biotic potential.

Psyllids damages to cultivated plants and forest timbers in Cameroon.

Joseph Lebel Tamesse[1], Victor Joly Dzokou[2], Wenceslas Yana[3]

[1]University of Yaounde I, Cameroon, [2]University of Yaounde I, Cameroon, [3]University of Yaounde I, Cameroon

Jumping plant-lice or psylloids form a moderate-size group of Sternorrhyncha (Hemiptera). They feed on plant sap, usually from the phloem, and are generally highly host specific.The present work describes the interactions between twenty psyllid species and their hosts in Cameroon. The damage that each psyllid species caused on its host has been described. Phytolyma fusca induced closed galls on leaves and buds of Milicia excelsa. These galls persisted during larval stages and exploded during the emergence of adults. Leaves and buds thus attacked dried and degenerated. Pseudophacopteron pusilum (on Dacryodes edulis), P. fuscovenosum (on Deimbolia sp.), P. nothospondiadis (on Nothospondias letestui), and Trioza sp. (on Schefflera barteri) induced closed and isolated galls on leaves of their respective hosts. Trioza erytreae (on citrus), Trioza sp. (on Stephania abyssinica) and Trioza sp. (on Drypetes leonensis) caused pit galls or crypts on leaves of their respective host.. Colophorina sp. (on Deutarium macrocarpum), Afrotrioza sp. (on Bersama sp.), Symtomosa sp. (on Homalium letestui), Pseudophacopteron cuniculus (on Bligia unijugata), and Diclidophlebia xuani (on Ricinodendron heudelotii) induced galls resulting from the enrolment of young leaves that hold larvae and adults. Psyllinae sp. (on Pittosporum viridiflorum); Triozamia sp. (on Antiaris Africana); Paurocephala sp. (on Dombeya ledermannii); Heteropsylla cubana (on Leucena glauca); and Trioza messii (on Caloncoba welwitchii) produced large quantities of honeydew responsible for the burns of the leaf tissue. The egg laying insertion mode of Mesohomotoma tessmanni caused some wounds in the leaf tissue of cocoa. Pseudoeriopsylla sp. attacked roots of Ficus thonningii.

The application of powdery preparation "Erdust" against bread ground-beetle (*Zabrus tenebrioides*) on wheat crops

Rakhmat Rasulov[1], Tulkin Ortikov[2], Sindor Pardayev[3]

[1]Samarkand Agricultural Institute, Uzbekistan, [2]Samarkand Agricultural Institute, Uzbekistan, [3]Samarkand State University, Uzbekistan

The bread ground-beetle (Zabrus tenebrioides) doesn't have a wide spreading in Uzbekistan and it is met in hearths. The harmfulness of larvae of bread ground-beetle depends not only on their number but on the nature of settling of sowings. At the centralized setting, even at high number of larvae, the sowing is lost not on the whole area. At a solid settling the existence of 3-4 larvae 1 m 2 they create a create threat and needs special destructive measures. Proceeding from mentioned above the strategy of struggle against bread ground-beetle is planned in the following way: - the processing of centres of damages; - conducting the solid processing; - presowing processing of seeds. Before conducting a solid processing of the centres of damages there were determined the forders of spreading larvae of bread ground-beetles, then there was conducted the processing with powdery preparation "Erdust" itsell counting 50kg/ha. The biological effectiveness of the preparation computed according to generally accepted methodics (in 3,5,7,10 days) was equaled to 93 %. On the plot with a solid setting of the pest there were used the preparation "Erdust" in the norm:50, 60 a 70 kg/ha. The best result was obtained in the variant with processing 70 kg/ha -92.9 %, which is higher than in variants 50 kg/ha (82 %) and 60 kg/ha (83,5) . The presowing processing was conducted by mixing moistented seeds of wheat with powdery preparation "Erdust" in the norm 15kg/t. The effectiveness of this method totaled 62,3 %.

Genetic modeling of the fipronil resistance's increase in the population of Colorado potato beetle

Konstantin Kitaev[1], Elena Surina[2], Maxim Udalov[3], Galina Benkovskaya[4]

[1]Institute of biochemistry and genetics of Ufa Scientific Center of Russian Academy of Sciences, Russia, [2]Institute of biochemistry and genetics of Ufa Scientific Center of Russian Academy of Sciences, Russia, [3]Institute of biochemistry and genetics of Ufa Scientific Center of Russian Academy of Sciences, Russia, [4]Institute of biochemistry and genetics of Ufa Scientific Center of Russian Academy of Sciences, Russia

We examine genetic model of population resistance to insecticides in the case Leptinotarsa decemlineata Say and fipronil. We use data about resistance in the population of Colorado potato beetle on the South Ural and data from the experiment of testing minimal dose of fipronil. The model show a difference two season in increase resistance between variants with recommended and minimal doses. We added in the model second sign (colour morph of vertex and pronotum). It influence mediately on other-wintering of resistant individuals and it may be sign of latent death this individuals. Model with two signs show more difference in increase resistance between variants with different doses. This model would to predict time of increase population resistance more exactly. We examine in the model variants with minimal dose of two insecticides alternating with each other. Model show the slowest increase of resistance. And we suppose this variant is optimal way of pest management in the case of Colorado potato beetle.. Investigations funded by RFBR, grants No 11-04-01886-r_povolzhie_a and 11-04-97022-a.

Examining the spatial and temporal factors that facilitate the distribution of *Halyomorpha halys* (Insecta: Hemiptera) in New Jersey, USA

Adam Wallner[1], Noel Hahn[2]

[1]*Rutgers University, U.S.A.*, [2]*Rutgers University, U.S.A.*

The brown marmorated stink bug (BMSB), Halymorpha halys (Stal), is an invasive pest of multiple fruit and vegetable crops in the mid-Atlantic region that has caused significant reductions in crop yield. It is native to China, Korea and Japan and was first found in the United States in Allentown, Pennsylvania in 1996. Since then, populations have been found in multiple states in the mid-Atlantic region, Midwest, and west coast, including but not limited to California, Michigan, New Jersey and Virginia. In New Jersey, the stink bug was first caught in 1999 in a black light trap. Additional catches have been collected and documented every year at geo-referenced traps across the state. This data will be displayed using Geographical Information Systems (GIS) to develop maps of distribution and density, with specific attention to population hot spots. These maps will provide an update on the movement and spread of brown marmorated stink bug and how these may be linked to nearby landscape and weather conditions.

Influence of weed management on occurrence of the two-spotted spider mite, Tetranychus urticae and the native predacious mite, Neoseiulus womersleyi in apple trees in northern Japan

Ken Funayama
Akita Fruit-Tree Experiment Station, Japan

To establish methods for successful IPM of Tetranychus urticae in orchards, the effect of weed management on the occurrence of this spider mite and Neoseiulus womersleyi on apple trees was investigated in 2009 and 2010 in an apple orchard in Akita Prefecture, northern Japan. Three plots differing in weed management were established in mid-April 2009; plot A: white clover sown and no mowing; B: mowing; C: no mowing. The chemicals sprayed were fungicides and insecticides that should not have affected the occurrence of both species. Mean number of T. urticae adult females on apple trees in plot C was significantly less than that in plot B in both years, and the number in plot A was significantly less than that in plot B in 2010. Neoseiulus womersleyi suppressed the increase of T. urticae on apple leaves in these plots when the density of T. urticae was low. The ground temperature during the daytime was comparatively stable in plot A and C, however that in plot B changed considerably. The maximum temperature on the ground in July in plot B exceeded 50°C. These observations suggest the possibility that the environmental conditions would remain suitable for T. urticae in vegetation not mowed and their immigrations into apple trees would be more reduced.

Efficacy of bio-pesticides for the management of of *Helicoverpa armigera* on chickpea in Central India

Chandra Bhushan Singh
Bundelkhand University, Jhansi, India

Pod borer, Helicoverpa armigera is a devastating pest of chickpea. We evaluated different combinations of biopesticides and natural plant products for the management of this pest in central India between 20008 - 2010. The treatments included: cow dung ash (CDA) (@40 kg/ha), garlic + tobacco leaf powder (GT) (500 g + 300 g), neem fruit powder extract (NFPE 5%), lime + cow dung + tobacco (LCT) (500 g + 15 kg + 5 kg) and H. armigera nuclear polyhedrosis virus (HaNPV). Untreated plots served as a control. All the treatments resulted in a significant reduction in H. armigera larvae compared to the untreated control. After three applications of bio-preparations/natural plant products, plots treated with HaNPV showed significantly greater reduction in larval population as compared to the plots treated with LCT. Plots treated with HaNPV, LCT, and NFPE 5% resulted in a significant reduction in pod borer damage as compared to the plots treated with CDA, and GT. The minimum pod damage 23.90% was recorded in plots treated with HaNPV, followed by the plots treated with LCT (27.03%), while NFPE 5% treated plots suffered 32.15% pod damage. The untreated plots suffered 54.59% pod damage. Highest yield of 17.46 q/ha was recorded in case of HaNPV treated plots, followed by 16.29 q/ha in plots treated with LCT, and these were significantly superior to the untreated control (11.43 q/ha). Based on these studies, HaNPV and LCT can be used for the management of H. armigera under moderate levels of pest attack.

Effect of selected doses of neem and pyrethrum based bio-pesticides on parasitism of *Liriomyza huidobrensis* (Blanchard) by *Phaedrotoma scabriventris* Nixon

Everlyne S. Namikoye[1], Adenirin Chabi-Olaye[2], Komi K. M. Fiaboe[3], Daisy Salifu[4], Callistus K. P. O. Ogol[5]

[1]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [2]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [3]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [4]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [5]Kenyatta University, Kenya

Liriomyza huidobrensis (Blanchard) is an important pest in vegetable production system in Kenya. Small scale farmers' routine application of synthetic pesticides induces resistance in the pest but decimate the natural enemies' complex. This study was carried out to evaluate the effect of neem (achook & neemroc) and pyrethrum based bio-pesticides on L. huidobrensis and its exotic parasitoid Phaedrotoma scabriventris Nixon. The three bio-pesticides significantly affect the adult L. huidobrensis' feeding and the survival rates of 1st and 2nd larval instars but had no effect on its oviposition and 3rd larval instar. The control registered the highest adult feeding and 1st and 2nd larval instars survival with 78.7±0.03 punctures/cm2, 90.0±1.7% and 92.0±6.6% respectively. The lowest feeding and survival rates of L. huidobrensis were recorded with Pyrethrum. Significant effects were recorded for doses ≥ 0.1, 0.5 and 0.5 for Achook, Neemroc and Pyrethrum respectively. The exposure of the 3rd larvae instar of L. huidobrensis to P. scabriventris with subsequent spray of respective bio-pesticides resulted in significantly higher pupal mortality compared to bio-pesticide use alone. While in the control, pupal survival and parasitism rates as high as 70.4±2.4% and 58.3±3.6 were obtained, at high concentration of Achook (0.25), they were as low as 11.1±1.1 and 8.0±1.5. The most suitable doses for a combined effect of the bio-pesticides and P. scabriventris were recorded at 0.05 for Achook, 0.25-0.5 for Neemroc and 0.125-0.5 for Pyrethrum. This suggests possibility of sustainable combination of bio-pesticides and the parasitoid P. scabriventris in the control of L. huidobrensis.

Suppression of fecundity, vitellin content and Nlvg gene expression in *Nilaparvata lugens* Stal (Hemiptera : Delphacidae) adult females exposed to sub-lethal dosages of indoxacarb and chlorantraniliprol

Jinglan Liu[1], Xia Yang[2]

[1]*Yangzhou University, China,* [2]*Yangzhou University, China*

The brown planthopper, Nilaparvata lugens (Stal) (Hemiptera: Delphacidae), is a classic example of a pest that experiences insecticide-induced fecundity with such compounds as pyrethroids (deltamethrin) and organophosphates (triazophos). The insecticides indoxacarb and chlorantraniliprole were recently developed with high insecticidal activity in the control of lepidopteran insects, including Tryporyza incertulas (walker) and Cnaphalocrocis medinalis (Guenee). In this study, we examined the changes in the fecundity of N. lugens, the vitellin contents in the fat bodies and ovaries and the vitellogenin (Nlvg) gene expression of adult females exposed to these new insecticides. Our findings showed that sub-lethal dosages of indoxacarb and chlorantraniliprole significantly suppressed the fecundity of the females. Treatment with 10, 20, 40 and 80 ppm indoxacarb decreased Nlvg mRNA expression by 35.4%, 74.4%, 79.6% and 61.9%, respectively, and treatment with 7.5, 15, 30, 60 and 80 ppm chlorantraniliprole decreased Nlvg mRNA expression by 79.3%, 40.2%, 40.0%, 79.8% and 51.8%, respectively. The vitellin contents in both the fat bodies and ovaries of the adult females also decreased, indicating that the two insecticides suppressed the synthesis of vitellin in the fat bodies and the transfer of vitellin to the ovaries. This decrease in the vitellin contents in the fat bodies and ovaries may be attributed to the low Nlvg expression. The study of the effects of indoxacarb and chlorantraniliprole on fecundity should have significance for the wide usage of these new insecticides in rice plants. Indoxacarb and chlorantraniliprole are ideal alternative insecticides to control T. incertulas and C. medinalis in China.

Keywords:*indoxacarb, chlorantraniliprole, Nilaparvata lugens, fecundity, vitellogenin mRNA gene expression*

Effects of commonly used synthetic pesticides in Pea production systems on *Liriomyza huidobrensis* and its parasitoids in Central Kenya

Mary M. Guantai[1], Komi K. M. Fiaboe[2], Callistus P. K. O. Ogol[3], Daisy Salifu[4], John M. Kasina[5], Adenirin Chabi-Olaye[6]

[1]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [2]International Centre of Insect Physiology and Ecology (ICIPE), Kenya, [3]Kenyatta University, Kenya, [4]International Centre for Insect Physiology and Ecology (ICIPE), PO Box 30772-00100, Nairobi, Kenya, Kenya, [5]Kenya Agricultural Research Institute (KARI), Kenya, [6]International Centre for Insect Physiology and Ecology (ICIPE), Kenya

Dimethoate, Dynamec, Thunder, Cyclone, Bestox, Folicur, Milraz and Bulldock are among the pesticides routinely used in the Pea production system in Central Kenya. Field and laboratory studies were carried out to assess their implication on the management of Liriomyza huidobrensis (Blanchard). On-farm field investigations consisting three management practices: farmers' routine use of pesticides (FP), reduced pesticide use (RP) and no pesticide use (CP) were conducted. Laboratory experiments were designed to test the effect of the pesticides on L. huidobrensis and two parasitoids Diglyphus isaea Walker and Phaedrotoma scabriventris Nixon. Liriomyza huidobrensis was more abundant in FP than CP and RP. Despite the constant presence of the pest, local parasitoids were only sporadically recorded, with CP recording higher numbers of parasitoids. Bestox, Cyclone and Dynamec were efficient in the laboratory against adult leafminer and their estimated LC50 (0.32, 0.5 and 0.24 ml/l respectively) were below the recommended doses. None of the pesticides were successful in controlling leafminer larva and the LC50 for Bestox, Bulldock, Dimethoate, Dynamec and Thunder (1.41, 1.64, 2.91, 1.16 and 2.94 ml/l respectively) were all above their recommended doses. Apart from Thunder which required 0.80 and 0.77 ml/l for LC50 for D. isaea and P. scabriventris respectively, all the pesticides were detrimental to the parasitoids at dosages below the recommended. This study demonstrated that routine pesticide use in farmer fields hampers effective control of L. huidobrensis since the pesticides eliminate the natural enemies without having any effective control on the larval stage of the pest.

Utilization Package of biological control agent of the green lacewing, *Mallada basalis* (Walker) (Neuroptera: Chrysopidae)

Rattigan Submok[1], Sopon Uraichuen[2], Anuchit Chinajariyawong[3]

[1]National Biological Control Research Center (NBCRC), Thailand, [2]Kasetsart University Kamphaeng Saen Campus, Nakhon Pathom, Thailand, [3]National Biological Control Research Center (NBCRC), Thailand

Study on the packages of the green lacewing Mallada basalis (Walker) (Neuroptera: Chrysopidae), aimed to find out the more applicable package for the release of this predator species for biocontrol. The primary trial was designed in 2×3×5 factorial experiment in completely randomized design with 25 replications, under laboratory condition at 25+2 OC, 75+2 % RH. The three factors were, factor I: tubes (0.5 cm in diameter x 7 cm in length) made of two types of material for confining the predatory eggs (1) plastic tube (2) white opaque A4 paper tube; factor II: two sizes of vermiculite and a mixture of the vermiculite, filled in the tubes (1) coarse (2) fine and (3) a mixture of coarse and fine (1:1) and factor III: five densities of eggs of the green lacewing, (1) 50 (2) 100 (3) 150 (4) 200 and (5) 300 eggs, enclosed in one either plastic or paper tube/replication. Results obtained showed that the main effects -type of material and egg density were not statistically significant (P>0.05), but size of vermiculite was (P<0.05). Only interaction of the main effects occurred between the main effects type of material and size of vermiculite. Hence, further analysis of variance indicated that mixture of coarse and fine vermiculite (1:1) in either plastic tube or paper tube gave the better hatching of eggs of M. basalis with 40.46±8.79 and 44.02±7.62%, respectively

Fumigant activity of plant essential oils from basil and spearmint on the Mediterranean flour moth *Anagasta kuehniella* Zeller (Lepidoptera : Pyralidae)

Panagiotis A. Iliopoulos[1], Christos N. Hassiotis[2], Stefanos S. Andreadis[3]

[1]Technological Educational Institute of Larissa, Greece, [2]Technological Educational Institute of Larissa, Greece, [3]Aristotle University of Thessaloniki, Greece

The fumigant activity of essential oil vapours distilled from sweet basil Ocimum basilicum and spearmint Mentha spicata (Lamiaceae) were tested against the Mediterranean Flour Moth. Various oil doses (5, 50, 250 and 500μl/lt air) and exposure times (0.5, 1 and 2 days) were tested during the present study. The essential oils were subjected to GC-MS analysis and revealed that the major compounds were for spearmint oil carvone (66.1%) and limonene (25.2%) and for basil oil estragol (71.7%) and linalool (17.7%). Generally, no significant differences on insecticidal action were noted between basil and spearmint oil. Both oils were highly effective against adult moths, given that 100% mortality was recorded after exposure to the lowest dose (5 μl/lt) for the shortest time interval (0.5 day). Noteworthy egg mortality was also recorded reaching at 73% for basil and 66% for spearmint. Toxicity data indicated that larvae and pupae were the most tolerant stages in all cases. Larval mortality never exceeded 30% and 26%, for basil and spearmint, respectively. Basil and spearmint oils managed mortalities as high as 31% and 21% in pupae, respectively. LC50 and LC99 (for 1 day exposure) as well as LT50 and LT99 (for each oil dose) values were estimated via probit analysis. Developmental stage proved to be a significant factor whereas the effect of oil species on insect mortality was insignificant. Basil and spearmint oils did not show satisfactory overall insecticidal activity against A. kuehniella, demonstrating much less toxicity than other essential oils from aromatic plants.

Diversity and seasonal activity of bark and ambrosia beetles in South Carolina, USA

Juang Horng Chong
Clemson University, U.S.A.

Bark and ambrosia beetles (Coleoptera: Curculionidae: Scolytinae) are important pests of horticultural, agricultural and forestry crops around the world. The diversity of the bark and ambrosia beetles in South Carolina, USA, is known but their seasonal activities are not. This study compared the diversity and seasonal activities of bark and ambrosia beetles in 3 distinct habitats in South Carolina - ornamental tree nursery (low plant diversity, low stand density), botanical garden (high plant diversity, low stand density) and pine-hardwood forest (high plant diversity, high stand density). Although the abundance of bark and ambrosia beetles captured in traps baited with ethanol and alpha-pinene was higher in the pine-hardwood forest, the diversity and seasonal activity were similar across the habitat types. Some species were active throughout the year but most species had distinctive peaks in their activity, typically in the spring or summer. Results from this study may help to improve the prediction of the flight activity of important bark and ambrosia beetle pests and the prevention of their attacks on economically important crop species.

Keywords:*Bark beetle, ambrosia beetle, ornamental trees, forest*

The economy of a suscessful ambrosia beetle management program in ornamental tree nursery

Juang Horng Chong
Clemson University, U.S.A.

The granulate ambrosia beetle, Xylosandrus crassisuculus (Motschulsky), is one of the most damaging insect pest species of ornamental tree nurseries in the southeastern United States. A management program based on moitoring with semiochemical and preventive applications of pyrethroid against this pest species was implemented in an ornamental tree nursery in Georgetown, South Carolina, USA. The management program reduced the percentage of susceptible trees damaged by the granulate ambrosia beetle from 13% in 2009 to 0.13% in 2010. The frequency of applications was reduced by 25% in 2010 due to a more precise timing of the applications. When the costs of control (material, labor and others) and damage were taken into account, the cost-benefit ratio of this program was 1:20. A similar program has been adopted for additional nurseries in the area.

Geographic variation among Colorado potato beetle populations and its implications for managing insecticide resistance

Andrei Alyokhin[1], David Mota-Sanchez[2], Mitchell Baker[3], Jie Chen[4], Mark Whalon[5]

[1]University of Maine, U.S.A., [2]Michigan State University, U.S.A., [3]City University of New York, U.S.A., [4]University of Maine, U.S.A., [5]Michigan State University, U.S.A.

Colorado potato beetle is the most important insect defoliator of potato in North America. It is an evolutionary plastic species, capable of adaptation to a variety of adverse conditions, including insecticide applications by humans. Management recommendations are often developed based on studies of as little as one Colorado potato beetle strain, often maintained under laboratory conditions over extended periods of time. A better understanding of geographic variability among Colorado potato beetle populations may eventually allow customizing control techniques to local conditions. Population growth potential, propensity for cannibalism, and levels, inheritance, and mechanisms of resistance to a commonly used insecticide imidacloprid were quantified under shared laboratory conditions in strains from different geographic locations. The differences in the number and size of produced egg masses, egg hatchability, and pre-oviposition period were detected among the strains. One of the strains had a female-skewed sex ratio, which is the first such record for this species. Not surprisingly, strains with high fecundity and low hatch rate had high cannibalism. There was a considerable variation in the strength of imidacloprid resistance among the locations. However, resistance had a similar monooxygenase-dependent mechanism (P450s) in all tested strains, and its inheritance was closer to recessive than to additive. Measured life history parameters did not correlate with strain resistance to insecticides. Geographical isolation appears to explain the observed variation.

Acaricidal bioactivity against *Tetranychus cinnabarinus* (Acari : Tetranychidae) of *Artemisia annua* extracts and their phytotoxicity on pest mites host plant cowpea

Yong-qiang Zhang[1], Wei Ding[2], Jin-xiang Luo[3], Zhen-guo Yang[4]

[1]Southwest University, China, [2]Southwest University, China, [3]Southwest University, China, [4]Southwest University, China

The acaricidal bioactivities of Artemisia annua extracts against the carmine spider mite Tetranychus cinnabarinus were confirmed. These extracts were the parallel and sequenced extracts of different solvents from the root, stem and leaf of Artemisia annua. And we found that the leaf acetone parallel extract showed the strongest acaricidal bioactivity, treatment after 48h at the concentration of 5mg/mL killed all test mites and the median lethal concentration (LC50) at 48h was 0.4341mg/mL. However, in order to clarify the toxic effects of these plant extracts on the seed germination rate and the radicle and hypocotyl growth inhibition of cowpea, which was principal host plant of the carmine spider mite. The concerned phytotoxicity tests against cowpea were also carried out in laboratory. The results showed that the impact of cowpea seed germination of Artemisia annua roots, stems and leaves extracts varied with the solvent species and different extraction methods. Of which the impact of stem ethanol sequenced extract against cowpea seed germination rate was greatest, and showed significant inhibition effect, and the germination rate was only 23.81%. Otherwise, the leaf acetone sequenced extract also showed strong inhibition effect on cowpea seed germination rate, of which the germination rate was 40.48%. The different solvent extracts of root stem and leaf of Artemisia annua in July were tested their phytotoxicity against cowpea seeds, and the results showed that weak inhibition effect on radicle and hypocotyl growth, and maybe also exist some material which promoting radicle, hypocotyl growth.

Cost-effectiveness of integrated pest management compared with insecticidal spraying against the German cockroach in apartment buildings

Gholam Hossein Shahraki[1], Dzolkhigli Bin Omar[2], Hafidzi Mohd Noor[3]

[1]Yasuj University of Medical Sciences, Iran, [2]University Putra Malaysia (UPM), Malaysia, [3]University Putra Malaysia, Malaysia

This study assessed the cost and effectiveness of an integrated pest management (IPM) program using hydramethylnon gel bait compared with conventional spraying method for controlling the German cockroach, Blattella germanica (L.) (Blattodea: Blattellidae), in two residential buildings in Yasuj, Iran. The IPM approach was based on educational programs using pamphlets, posters and lectures, sanitation using vacuuming and application of hydramethylnon gel bait. Conventional approach used spray of cypermethrin (10% EC) on baseboard and cracks-and-crevices. Sticky traps were used as tools for monitoring cockroach populations throughout 15 weeks treatment periods.The IPM approach reduced (943%) the rate of insecticide application compared to the conventional spray. Cockroach populations in the IPM treatment were significantly reduced from an average of 12.2 ± 3.01 cockroaches per unit before treatment to zero cockroach per unit by week four and thereafter. Cockroach populations in the conventional spray treatment were reduced from an average of 11.5 ± 4.43 cockroaches per unit before treatment to an average of 3.4 ± 0.99 cockroach per unit after 11 weeks of post treatment. The IPM treatment improved 100% of infested units compared to 78% for spray treatment to obtain a clean level of infestation (<1 cockroach per trap per unit). The results suggest that the intervention by IPM using hydramethylnon gel baits significantly reduced cockroach infestation compared to cypermethrin spray throughout the 11 weeks of post-treatment period. However, within the study period, the IPM system involving gel baits, educational program and sanitation was 363.2% more expensive than the conventional method.

Contact activities of extracts from different parts of *Phytopacca americana* L. against *Tetranychus cinnabarinus* (Boisduval) (Acarina:Tetranychidae)

Li-juan Ding[1], Wei Ding[2], Yong-qiang Zhang[3]

[1]*Southwest University, China,* [2]*Southwest University, China,* [3]*Southwest University, China*

The different solvent extracts from different parts of Phytolacca americana L. were tested for their acaricidal activities against female adults of carmine spider mite, Tetranychus cinnabarinus (Boisduval), by slide-dip bioassay. The results indicated that acetone extract of the root was more active than that from leaves and stems at 48 h and 72 h after treatment, and other solvent extracts from any organs, and it exhibited strongest activity against female adult, causing 95.72% to 100.00% mortality in 72 h at the concentration of 2.5 mg?ml-1 after treatment, meanwhile, the LC50 values of eggs and female mites were 2.1637 and 7.1032 mg ml-1, respectively. The acetone root extract was fractionated using a silica gel column, after thin layer chromatography, the concentrated extract was separated into 15 groups of fractions and further tests for their acaricidal activities were conducted. Fraction 9 was found to possess higher acaricidal activity. At the concentration of 2 mg ml-1, the corrected mortalities of the fraction 9 against adult mites were 60.84% and 95.75% in 12h and 24h after treatment, respectively. The LC50 values of the fraction 9 were 1.2609, 0.2035 and 0.1026 mg ml-1 after treatment 24h, 48h and 72 h, respectively. The 9th group was identified as one potent acaricidal saponins through the phytochemical test. From the qualitative determination of the saponins, it is concluded that the acaricidal saponins is a type of oleanane triterpenoidal saponins.

Bio-ecology of the red palm weevil, *Rhynchophorus ferrugineus* Olivier (Coleoptera: Curculionidae)

Oscar Dembilio[1], Josep Anton Jacas[2]

[1]Universitat Jaume I (UJI), Spain, [2]Universitat Jaume I (UJI), Spain

The red palm weevil, Rhynchophorus ferrugineus, is the most destructive pests of palms in the world. In the Mediterranean the Canary date palm, Phoenix canariensis, has become the main host of this weevil. For this reason we carried out a study aimed at determining the life cycle of R. ferrugineus in live P. canariensis palms. Egg lethal temperature threshold and thermal constant were determined and resulted in 13.10ºC and 40.4 DD, respectively. A semi field assay was carried out in a mesh enclosure where living P. canariensis palms were artificially infested with neonate larvae under natural conditions. Maximum mortality rates for R. ferrugineus were observed for palms infested in December and January, whereas those infested from April through September showed maximum survival rates. Mean monthly temperatures below 10.30ºC were lethal for neonate larvae, as 4.50ºC were for older instars. All recovered larvae could be classed according to one of thirteen instars. A thermal constant of 666.5 DD was estimated for complete larval development. Pupal development required an additional 282.5 DD. To better understand the phenology of R. ferrugineus populations in the Mediterranean basin, we have estimated the effect of temperatures within the range 10-25ºC on the reproductive parameters of R. ferrugineus. Our results confirm that oviposition is strongly affected by temperature. Thresholds for oviposition and egg hatching (15.45º and 13.95ºC, respectively) are very close to mean annual temperatures registered in most of the northern shore of the Mediterranean basin. These results should help refining existing control strategies against this pest.

Ground cover management affects species composition, distribution, and seasonal abundance of Thysanoptera occurring in citrus.

Ernestina Aguilar-Fenollosa[1], Josep Anton Jacas[2]

[1]Universitat Jaume I (UJI), Spain, [2]Universitat Jaume I (UJI), Spain

There is a complex of Thysanoptera species inhabiting citrus and some of them are considered pests. This study was aimed at studying the effect of ground cover management on thrips species composition, distribution and seasonal abundance in commercial clementine mandarin orchards. Three soil management systems were compared: resident vegetation cover, Festuca arundinacea Schreber (Poales: Poaceae) cover, and bare soil. The ground cover influenced the abundance of some thrips in the cover. Among the main species causing fruit damage in citrus, we found Frankliniella occidentalis (Pergande) and Thrips tabaci Lindeman. The F. arundinacea cover strongly depressed the abundance of these thrips species in ground cover vegetation. The resident vegetation cover could provide a range of suitable hosts supporting populations of potential thrips pest species out of the main citrus peak blooming period. Apart from that, the F. arundinacea cover, which hosted Poaceae-specific thrips species, could provide alternative food enhancing populations of predatory phytoseiid mites which could reduce populations of potential citrus pests below economic injury level. Our results confirm the suitability of F. arundinacea as a cover crop for clementine mandarins

Life history parameters for *Nesidiocoris tenuis* Reuter and *Macrolophus pygmaeus* (Rambur) (Hemiptera: Miridae) preying upon *Tuta absoluta* (Meyrick) (Lepidoptera: Gelechiidae)

Oscar Molla[1], Miquel Alonso-Valiente[2], Alberto Urbaneja[3]

[1]*Instituto Valenciano de Investigaciones Agrarias (IVIA), Spain,* [2]*Instituto Valenciano de Investigaciones Agrarias, Spain,* [3]*Instituto Valenciano de Investigaciones Agrarias (IVIA), Spain*

The polyphagous predators Nesidiocoris tenuis Reuter and Macrolophus pygmaeus (Rambur) (Hemiptera: Miridae) are endemic natural enemies that commonly inhabit tomato crops in the Mediterranean basin. Both predators are mass-reared and, until recently, they were mainly released to control whiteflies. However, both mirids have been observed to prey efficiently on the eggs of the invasive tomato pest Tuta absoluta Meyrick (Lepidoptera: Gelechiidae). In this study, the life-history traits of these two predators were studied and compared when they were fed exclusively with eggs of T. absoluta on tomato plants. The experiments were performed under laboratory conditions (25 ºC, 60% RH and 16:8 h L:D). The immature survival for both mirids was similar (?90%), although the nymphal development time was significantly faster for N. tenuis than for M. pygmaeus (13.0 ± 0.1 d and 16.0 ± 0.2 d, respectively). The progeny was also higher for N. tenuis than for M. pygmaeus (38.9 ± 6.9 and 3.0 ± 1.7 nymphs per female, respectively). These differences resulted in higher selected life history parameters for N. tenuis when compared to M. pygmeus (e.g. the intrinsic rate of increase was 0.135 for N. tenuis and 0.006 for M. pygmaeus). Our results, may explain the higher efficacy of N. tenuis controlling T. absoluta and the increasing prevalence of N. tenuis in those tomato crops infested by T. absoluta.

Molecular evaluation of sterile *Ceratitis capitata* males performance in field cages: Correlation of mate achievement and fruit damage avoidance

Maria A. Juan-Blasco[1], Beatriz Sabater Munoz[2], Maria V. Ibanez-Gual[3], Rafael Argiles[4], Josep A. Jacas[5], Pedro Castanera[6], Alberto Urbaneja[7]

[1]Instituto Valenciano de Investigaciones Agrarias (IVIA), Spain, [2]Instituto Valenciano de Investigaciones Agrarias (IVIA), Spain, [3]Universitat Jaume I (UJI), Campus del Riu Sec, Castello de la Plana, Spain, [4]Empresa de Trasnformaciones Agrarias (TRAGSA), Paterna, Spain, [5]Universitat Jaume I (UJI), Campus del riu sec, Castello, Spain, [6]Centro de Investigaciones Biologicas (CIB), CSIC, Madrid, Spain, [7]Instituto Valenciano de Investigaciones Agrarias (IVIA), Moncada, Spain

In area-wide Sterile Insect Technique (aw-SIT) programs there is a lack of real-time information about how the success of the sterile male releases is translated in pest population reduction. Recently described field cage tests have demonstrated the possibility to relate the molecular sterile sperm ID in the spermathecae of C. capitata females with the fruit damage. Field cage tests were carried out to study the activity of sterile Vienna-8 (V8) males under six release ratios (1:0:0, 1:1:0, 1:1:1, 1:1:5, 1:1:10 and 1:1:20; wild females: wild males: V8 males) and their efficacy in population reduction under different environmental conditions in the Mediterranean coast of Spain. The data collected were the recaptured females in traps, sperm ID in the spermathecae of trapped females, and the viable progeny produced. Data showed the significant effect of temperature (as environmental variable) and sterile males release ratio correlated on the V8 performance (sperm transference and progeny reduction). During the winter neither was identified male sperm in spermathecae nor was obtained progeny. Out of the winter, the proportion of V8 sperm ID in spermathecae was similar for the ratios 1:1:10 and 1:1:20 which was the highest compared to 1:1:0 over all the temperatures tested. Moreover, the progeny reduction showed to be strongly related with the proportion of V8 sperm ID in females independently of release ratios and environmental conditions. The models obtained based on molecular sperm ID could contribute to enhance the measurement of the efficacy of SIT programs.

Novel insect toxins from two scorpions inhabiting Japan, *Liocheles australasiae* and *Isometrus maculatus*

Yoshiaki Nakagawa[1], Masahiro Miyashita[2], Hisashi Miyagawa[3]

[1]Kyoto University, Japan, [2]Kyoto University, Japan, [3]Kyoto University, Japan

Scorpions are venomous animals and many thousands of people are stung worldwide and hundreds are died in the world. Two scorpion species, Liocheles australasiae (Hemiscorpiidae) and Isometrus maculatus (Buthidae), inhabit the southern islands of Japan. Even though we have not suffered serious damage from them, scorpions are utilizing venoms to catch insects. To date, we isolated two toxins from L. australasiae (LaIT1 and LaIT2) and three toxins from I. maculatus (Im-1, Im-2, and Im-3) by repeating HPLC fractionation and monitoring the insecticidal activity against cricket. Primary structures of these toxins were determined using mass spectrometry and Edman degradation as well as cDNA cloning. LaIT1 is composed of 36 amino acids with two disulfide bonds and shows no sequence homology to any other known toxins. LaIT2 is of 59 amino acids with three disulfide bonds and homologous to β-KTx affecting potassium channel. Im-1 is linear peptide with 56 amino acids without cysteine residues. Im-2 is composed of 67 amino acids and Im-3 is of 63 amino acids, and both of them contain 4 disulfide bonds. The patterns of disulfide linkage of LaIT2, Im-2 and Im-3 are not analyzed yet. LaIT2 and Im-1 have also anti-bacterial activity. Im-2 and Im-3 are homologous to the toxins affecting Na-channel. Im-2 is excitatory toxins and also toxic to mammals, but Im-3 is depressant toxins. We analyzed the three-dimensional structure using NMR to find that the structure has the knotting peptide motif, and studied the structure activity relationship of LaIT1 and its analogs.

Botanical extracts in northeastern Brazil: Biological alternative to pest control in fruit species

Marcone Cesar Mendonca Chagas[1], Ernesto Espinola Sobrinho[2], Tiago Cardoso Costa Lima[3]

[1]Brazilian Agricultural Research Corporation - EMBRAPA, Brazil, [2]Emparn, Brazil, [3]Brazilian Agricultural Research Corporation - EMBRAPA, Brazil

The agriculture is one of the activities with more impact over the environment. In northeastern Brazil, it has been evidenced the necessity to optimize the exploration system of some fruit species, with notability to the following cultures: cashew (Anacardium occidentale), mango (Mangifera indica), guava (Psidium guajava), papaya (Carica papaya) and coconut (Cocos nucifera). Research results show the botanical extracts efficiency, especially oils as alternative to chemical insecticides. The management of the coconut pest species Aceria guerreronis (Acari: Eriophyidae), Atheloca subrufella (Lepidoptera: Phycitidae) and Parisoschoenus obesulus (Coleoptera: Curculionidae) have been adopted successfully by the major coconut producing areas in Brazil, using the aqueous solution: cotton oil (1.5%) and neutral detergent (1.0%). Similar results were obtained in cashew controlling the whitefly, Aleurodicus cocois (Hemiptera: Aleyrodidae). The use of the plant oil mixture, cotton (1.5%), castor (1.5%) and neem (1.0%) and/or mineral oil (1.0%) in different interval of 3 and 4 weeks, has brought positive results in the control of Trizoida sp. (Hemiptera: Psyllidae), Frankliniella schultzei (Thysanoptera: Thripidae) and Tetranychus urticae (Acari: Tetranychidae), respectively, in guava, mango and papaya. The cost to control these pests reduced up to 75% and was noticed a fast recovery of the natural enemies population in the studied areas.

Employing pheromone traps for seasonal monitoring of the potato tuber moth, *Phthorimaea operculella* (Zeller) (Lepidoptera: Gelechiidae) in Bulgaria

Mitko Subchev[1], Teodora B. Toshova[2], Daniela I. Atanasova[3], Vilina D. Petrova[4], Miklos Toth[5]

[1]Institute of Biodiversity and Ecosystem Research, BAS, Bulgaria, [2]Institute of Biodiversity and Ecosystem Research, BAS, Bulgaria, [3]Agricultural University, Plovdiv, Bulgaria, [4]Institute of Agriculture, Kyustendil, Bulgaria, [5]Institute of Plant Protection, HAS, Budapest, Hungary

Two year seasonal monitoring of the flight of Phthorimaea operculella by means of pheromone traps was organized at four sites in three districts in Bulgaria: Sofia, Kyustendil and Plovdiv. Comparison between sticky traps and dry funnel traps has shown that sticky traps were much more effective in capturing of males of this pest than the dry ones. The results of our investigations showed that the pest could appear in the field as early as the end of March and also intensive flight could be observed up to the end of November. Single catches were registered even in January. However, because of overlapping of the generations, their number and periods of moth emergence was not possible to be distinguished by the catches in pheromone traps. Analyses of climatic data (mean air temperature and mean rainfall) indicated that none of the climatic variables investigated strongly affected P. operculella trap catches. Acknowledgments: The research was supported by Grant DO02-244/2008 of the Bulgarian National Scientific Fund.

Optimum predation temperature and pesticide susceptibility of the predatory bug, *Geocoris proteus* Distant (Heteroptera: Geocoridae)

Yuta Tsuchida[1], Shinichi Masui[2], Yusuke Katai[3], Akio Tatara[4]

[1]Shizuoka Prefecture Agriculture and Forestry Research Institute, Japan, [2]Shizuoka Prefecture Agriculture and Forestry Research Institute, Japan, [3]Shizuoka Prefecture Agriculture and Forestry Research Institute, Japan, [4]Shizuoka Prefecture Agriculture and Forestry Research Institute, Japan

The big-eyed bug Geocoris proteus Distant has been observed on Allium crops in western Shizuoka Prefecture. The bug is an important predator of several economic pests of various crops in the field. We investigated the optimum temperature for prey consumption and also the bug's pesticide susceptibility. First, adult and 3rd-instar larvae of G. proteus were provided with Thrips tabaci at 15, 20, 25, or 30 °C for 24 h. Geocoris proteus consumed the maximum numbers of prey consumed at 25 and 30 °C. (Adult female G. proteus preyed on about 80 2nd-instar larvae of T. tabaci.) These results suggest that G. proteus has high predatory potential and that high temperatures are suitable for predation. Second, G. proteus adults or 3rd-instar larvae were dipped into 66kinds of pesticide solution with practical concentration in labo. Two organophosphorus insecticides, 1 carbamate, 2 neonicotinoids, 2 insect growth regulators, 8 synthetics, 1 natural product based insecticide, 5 microbial insecticides, 4 acaricides, and 14 fungicides were rated as harmless (< 30% mortality) to the adults and 3rd-instar larvae. These pesticides are therefore compatible with G. proteus conservation in the field, and their use should be recommended in integrated pest management programs to control Allium insect pests.

Individual-based model for the spread of citrus greening disease by the vector insect *Diaphorina citri*

Youichi Kobori[1], Fugo Takasu[2], Yasuo Ohto[3]

[1]Japan International Research Center for Agricultural Sciences, Japan, [2]Nara Women's University, Japan, [3]National Agriculture and Food Research Organization, Japan

Citrus greening disease (Huanglongbing, HLB) is an untreatable insect-borne disease that makes trees withered and dies. The IPM system which is focused on the vector insect is required for reducing the economic loss. To establish an IPM system, risk assessment of the relevant hindrances is necessary. Applying simulation model to the estimation is one of the reasonable risk evaluation methods. Thus, we developed a model which estimates the spread of HLB by the vector insect Diaphorina citri. Until quite recently, almost all models of pathogens and hosts were developed within the framework of mean-field models, which assumed uniform distribution and interactions of the respective individuals. In recent years, however, the increased calculation speed of computers has enabled the development of an Individual-Based Model (IBM), wherein each individual, of the pathogen and the vector, behave individually, acting according to a predefined set of rules. IBM is able to examine disease-spread dynamics in consideration of space, by calculating the cumulative results of the individual behaviors. Hence, we used the framework of IBM to establish the HLB spread model. Our simulated results suggested that both delaying the transition from latent period to infectious period, and removing infectious citrus trees, suppressed the HLB spread rate in an orchard. Additionally, the results of our a preliminary trail suggested that cooperative control of D. citri on the part of orchard owners in a given area, reducing the number of virulent individuals was effective in suppressing the HLB spread rate.

The association of a Lepidopteran borer complex between pecan nuts (*Carya illinoensis*) and citrus (*Citrus sinensis*) in the vaalharts region

Andre Petrus van Rooyen[1], Vaughn Richmond Swart[2], Sean Moore[3]

[1]University of the Free State, South Africa, [2]University of the Free State, South Africa, [3]Citrus Research International, South Africa

The possible migration of economically important Lepidoptera borer species from citrus (Citrus sinensis) to pecan nuts (Carya illinoensis), and vice versa, at Vaalharts, Northern Cape is investigated. Possible species of interest within the lepidopteran borer complex, which are established pests on citrus and pecan nuts, false codling moth Thaumatotibia leucotreta (Meyrick, 1913) (Lepidoptera: Tortricidae) and carob moth Ectomyelois ceratoniae (Zeller, 1839) (Lepidoptera: Pyralidae). The incidence of the two lepidopteran species in pecan orchards, in proximity to citrus orchards, is compared to pecan orchards remote to citrus orchards. Approximately, 100 pecan nuts and 50 citrus fruit (from the trees and ground) were collected from adjacent orchards, 10 and 50 m from the edge of pecan and citrus orchards. Five farms that met these conditions were selected as study sites. The samples were placed into emergence boxes to allow the immatures to develop to adulthood. The incidence of the two lepidopteran species relative to the distance of the pecan and citrus orchards from each other will determine the extent to which the migrations may occur. The higher proportion of E. ceratoniae (55%) was recorded in the pecan study sites proximal to citrus orchards, with a lower incidence (45%) in the remote pecan control sites. Citrus orchard study sites had incidence of only E. ceratoniae. Thaumatotibia leucotreta was present in two of the pecan orchards. Ectomyelois ceratoniae is the dominant of the two pest species under investigation. Proximity of citrus orchards don't seem to increase the incidence of E. ceratoniae in pecan orchards.

Integration of bean resistance and a botanical insecticide (neem formulation) to manage the Mexican bean weevil.

Danilo Akio de Sousa Esashika[1], Tamiris Alves de Araujo[2], Jessica Goncalves Sousa[3], Antonio Macedo Dias[4], Cristina Schetino Bastos[5]

[1]UnB-Universidade de Brasilia, Brazil, [2]UnB-Universidade de Brasilia, Brazil, [3]UnB-Universidade de Brasilia, Brazil, [4]UnB-Universidade de Brasilia, Brazil, [5]UnB-Universidade de Brasilia, Brazil

Considerable losses occur in stored beans in Brazil due to the attack of key pests such as Zabrotes subfasciatus (Coleoptera: Bruchidae), which is able to cause cross-infestation of grains. The goal of this work was to evaluate the preference of Z. subfasciatus by six different kinds of beans belonging to the genus Phaseolus, Vicia and Vigna and how a neem formulation could help preventing damage in the tested grains. In order to achieve that, the six tested genotypes were arranged in an arena inside of a cage and 60 non-sexed insects were released in the center. Coffee cups containing 20g samples and arranged in a completely randomized design with five replicates were evaluated for the number of insects 0.5, 1, 2, 4, 6, 12, 22, 30 and 48h after the initial release. The number of damaged grains was evaluated at the end of the essay. The data were analyzed by repeated measures analysis and the results were used to select the genotypes to be further tested in three other bioassays using the neem formulation at 10% of concentration and water as control. The results showed that while the genotype 'fradinho (Vigna unguiculata)' was the most preferred followed by 'vinagre (Phaseolus vulgaris), the genotypes 'preto (P. vulgaris)', 'fava amarela and fava rajada (Vicia faba)' and 'corda sempre verde (V. unguiculata) were the less preferred by Z. subfasciatus. The treatment with neem reduced the number of insects and damaged grains by almost zero even in the highly preferred genotypes.

The boll weevil (BW - Anthonomus grandis) is a highly harmful pest of cotton in Brazil where it is widespread and causes significant economical losses. This work aimed at evaluating the control of BW obtained by the association of plant resistance and mass trapping or chemical control with a botanical insecticide (neem formulation). For that purpose, natural colored cotton (BRS Rubi, Safira and Topazio) were cultivated isolated or surrounded by a white cotton (BRS Aroeira) which is known to be BW-resistant. Each plot was BW controlled by either mass trapping (one accountrap + pheromone/plot) or by spraying a neem formulation (at increasing concentrations of 0.5, 1 and 2%). The neem formulation was used every time that the infestation level (IL) reached 10%. Plots were weekly sampled, starting at 90 days after sowing. The association of the colored cotton Rubi with the white cotton Aroeira reduced the need to spray with neem in more than 50%. Although the same did not happen to Safira and Topazio, the IL was smaller in the plots cultivated with these varieties, surrounded by Aroeira and sprayed with neem. Concerning the mass trapping, the number of times BW reached the IL did not vary among the plots surrounded or not by the white cotton, but the IL was always smaller in the former and, mostly, smaller than in the same plots sprayed with neem. The number of squares and bolls damaged by BW was maximum in BRS Rubi and minimum in BRS Safira and Topazio.

Attractiveness of blue and ultraviolet light-emitting diodes to *Thrips palmi* Karny

Yusuke Katai[1], Shinichi Masui[2], Yuta Tsuchida[3], Akio Tatara[4]

[1]Shizuoka Prefecture Agriculture and Forestry Research Institute, Japan, [2]Shizuoka Prefecture Economy and Industry Department, Japan, [3]Shizuoka Prefecture Agriculture and Forestry Research Institute, Japan, [4]Shizuoka Prefecture Agriculture and Forestry Research Institute, Japan

To develop a method for physical control of Thrips palmi Karny, we investigated the ability of visible and ultraviolet light-emitting diodes (LEDs) to attract the insect. LEDs emitting blue (peak wavelength: 470 nm) and green (peak: 525 nm) visible light attracted significantly larger numbers of T. palmi than other LEDs. UV-LEDs (peak: 365 nm) were more efficient than blue LEDs. Mixing blue and UV LEDs did not increase the proportion of T. palmi trapped.

Energy-saving light trap for cigarette beetles using flickering UV-LED.

Naoto Fukazawa[1], Satoshi Tsuchiya[2], Hirohide Iwamoto[3], Ryota Takahashi[4]

[1]Japan Tobacco Inc., Japan, [2]Japan Tobacco Inc., Japan, [3]Japan Tobacco Inc., Japan, [4]Japan Tobacco Inc., Japan

Adult cigarette beetles exhibit positive phototactic response, especially to UV light, and can therefore be captured in light traps. The influence of the flicker-frequency of light on photoresponse has been demonstrated for some insect species, but no information exists for the cigarette beetle. This study examines the influences of light flicker-frequency and duty cycle on cigarette beetle capture using a light trap to evaluate the practical value of flickering UV-LED light for the cigarette beetle. In dark conditions, 100 adult beetles were released in a 1.8 × 3.6 × 1.8 (H) m chamber kept at 29°C. A water-pan trap (20 × 68 cm) equipped with a UV-LED lamp emitting light (375 nm) with a controlled flicker-frequency and duty cycle was used to catch light-lured beetles. No significant difference was found between catches achieved with traps emitting flickering light (50% duty cycle) at a flicker-frequency of 50, 100, 150, 200, 300, 500, or 1000 Hz and those with traps emitting non-flickering light. Furthermore, no difference in catches was observed between light traps that emitted non-flickering light and those emitting light with a controlled duty cycle (20, 30, 40, 50%; 200 Hz). Results indicate that light traps with flickering UV-LED (50-1000 Hz, 20% duty cycle) can be operated with 20% of the electricity consumption of non-flickering UV-LED traps without reduced attractiveness to cigarette beetles.

Effect of flonicamid on voltage-gated potassium currents

Hiroshi Shikama[1], Shogo Atsumi[2], Chiaki Takeda[3], Shuichi Yotsuya[4], Kiyomitsu Yoshida[5], Tomohisa Ishikawa[6]

[1]Central Research Institute, Ishihara Sangyo Kaisha, Ltd., Japan, [2]Central Research Institute, Ishihara Sangyo Kaisha, Ltd., Japan, [3]Central Research Institute, Ishihara Sangyo Kaisha, Ltd., Japan, [4]Central Research Institute, Ishihara Sangyo Kaisha, Ltd., Japan, [5]Central Research Institute, Ishihara Sangyo Kaisha, Ltd., Japan, [6]School of Pharmacutical Sciences University of Shizuoka, Japan

Flonicamid is a pyridinecarboxamide compound invented and globally developed by Ishihara Sangyo Kaisha, Ltd.; and is characterized by its inhibiting effects on sap-sucking behavior of aphids and other sucking insect pests at low application dose rate. We focused on its unique activity which provides some species with abnormal motions and behaviors, and investigated its mode of action by using the whole-cell patch clamp technique. Flonicamid inhibited whole-cell outward currents evoked by voltage steps in a primary culture of ganglion cells of Spodoptera litura. In the study with the transformant in which the fast-inactivating A-type potassium channel (Kv4.3) was introduced, flonicamid did not show any inhibitory effect. The inhibition of outward currents observed in the ganglion cells of S litura seemed to be due to an inhibition of outward currents through delayed-rectifier potassium channels, such as seizure (sei), ether-a-go-go (eag), shaker cognate b (shab), shaker cognate w (shaw) or slowpoke (slo). Abnormal behaviors and defects in courtship song have been reported in Drosophila with mutations in the eag and slo genes, respectively. An inhibition of sap-sucking, abnormal behaviors and mating disruption are also observed in insect pests treated with flonicamid (Aphididae, Cicadellidae, Cixiidae and Drosophila). Taken together, the effects of flonicamid are suggested to be associated with the inhibition of delayed-rectifier potassium channels.

Keywords:*flonicamid, whole-cell patch clamp, delayed-rectifier potassium channels*

Eradication of the solanaceous fruit fly, *Bactrocera latifrons* (Hendel) (Diptera: Tephritidae), from Yonaguni Island, Okinawa, Japan

Takashi Matsuyama[1], Tsuguo Kohama[2], Chihiro Miyazato[3], Hiroyuki Kuba[4], Noriaki Mougi[5], Aya Kobayashi[6]

[1]Okinawa Prefectural Plant Protection Center, Japan, [2]Okinawa Prefectural Agricultural Research Center, Japan, [3]Okinawa Prefectural Agricultural Research Center, Japan, [4]Okinawa Prefectural Agricultural Research Center, Japan, [5]Okinawa Prefectural Agricultural Research Center, Japan, [6]Okinawa Prefectural Agricultural Research Center, Japan

The solanaceous fruit fly, Bactrocera latifrons (Hendel), is known as a serious pest of solanaceous crops. This is widely distributed throughout South and South-East Asia, and is locally distributed in Hawaii and Africa. In Japan, It was first detected on Yonaguni Island (2,888ha) located in the westernmost island of Japan in 1984. There is concern that B. latifrons could spread to the south islands of Japan with shipped host fruits and/or the movement of adult flies. Therefore, eradication project for B. latifrons using sterile insect technique (SIT) was urgently implemented in 2004. Firstly, protein bait and clean culture methods were applied to suppress the wild population before implementation of the SIT. Mass release of sterile flies was initiated in Sep. 2007. About 400,000 sterilized insects were marked with fluorescent powder dye and released throughout the Yonaguni Island every week. Yellow sticky trap surveys were conducted from Oct. 2004 to Mar. 2010, and host fruit-surveys were conducted until Mar. 2011 to evaluate the control methods. The last detection of wild B. latifrons was in Mar. 2009 in host fruits-surveys. After that, no wild flies were found from host fruits-surveys for two years, in which 331,708 fruits were collected from 1,295 points throughout the Yonaguni Island. In addition to our surveys, Japanese government confirmed the eradication by their surveys of host fruits (170,863 fruits from 367 points) from Apr. to May. 2011. Altogether, B. latifrons was successfully eradicated from Yonaguni Island.

Do closely related plants play a role in enhancing problems caused by *Meligethes aeneus* Fab?

Riina Kaasik[1], Gabriella Kovacs[2], Luule Metspalu[3], Eve Veromann[4]

[1]Estonian University of Life Sciences, Estonia, [2]Estonian University of Life Sciences, Estonia, [3]Estonian University of Life Sciences, Estonia, [4]Estonian University of Life Sciences, Estonia

The presence of other cruciferous plants is usually undesired in oilseed rape fields. In this study we carried out small size plot experiments in 2006?2008 to test whether Brassica juncea and Sinapis alba are more attractive to the pollen beetle (Meligethes aeneus), do they allure more of this pests to the oilseed rape fields thereby increasing the damage caused. Furthermore, we tested the suitability of Brassica rapa as a trap crop protecting Brassica napus. We also investigated the impact of host plants on the oviposition preferences of parasitoids attacking the pollen beetle. According to our results none of the tested plant species increased the pest infestation of oilseed rape. On the contrary, both host plant species even decreased the damage caused by pollen beetles because they lured beetles at the most damage-susceptible stage of oilseed rape plants. Additionally, the parasitism rate was the highest on B. juncea and did not significantly differ between S. alba and B. napus. Thus, we can assume that close relatives of oilseed rape can also support the presence of natural enemies of pests in the field. The parasitism rate of the pollen beetle was surprisingly high, it reached up to 64.7% on B. juncea. Additionally the species composition of parasitoids of M. aeneus differed among plant species.

Fatal attractiveness? Host plant may kill its enemy's offspring

Eve Veromann[1], Riina Kaasik[2], Gabriella Kovacs[3], Luule Metspalu[4]

[1]Estonian University of Life Sciences, Estonia, [2]Estonian University of Life Sciences, Estonia, [3]Estonian University of Life Sciences, Estonia, [4]Estonian University of Life Sciences, Estonia

Manipulation with attractiveness of host plants to insect pests is a useful tool in ecologically sustainable and economically viable integrated crop management. There is a growing interest in the value of enhanced agro-ecosystem diversity and "push-pull" strategies for suppression of insect pests. Plants that are suitable for feeding and oviposition but do not offer safe environment for development are called dead-end trap-crops. We compared oviposition activity and larval survival of Meligethes aeneus on the buds of Brassica napus, B. rapa, B. nigra, B. juncea, Eruca sativa, Raphanus sativus and Sinapis alba to find a potential trap-crop for oilseed rape. The number of M. aeneus eggs in green buds (BBCH 51?53) was lower on S. alba than on all other plants. The number of larvae in yellow buds (BBCH 59) on B. napus, B. nigra, B. juncea and R. sativus was greater than on B. rapa, E. sativa and S. alba. Brassica rapa was more attractive than E. sativa and S. alba but less than B. napus and B. nigra. Dead larvae were found only on E. sativa and R. sativus. The number of dead larvae on E. sativa was lower than number of alive larvae. The ratio of dead and alive larvae on R. sativus was almost equal, the average mortality was 46%. In conclusion, R. sativus had similar attractiveness as B. napus as an oviposition site for M. aeneus than oilseed rape, but perform as dead-end trap-crop because almost half of the larvae could not survive.

Keywords:*Meligethes aeneus, dead-end trap-crop, Brassica napus, B. rapa, B. nigra, B. juncea, Eruca sativa, Raphanus sativus, Sinapis alba, oviposition*

BICOPOLL: Targeted precision biocontrol and enhanced pollination

Heikki Hokkanen[1], Otto Boecking[2], Andrej Cokl[3], Belen Cotes[4], Cafer Eken[5], Reet Karise[6], Jasna Krajl[7], Bettina Maccagnani[8], Ingeborg Menzler-Hokkanen[9], Veerle Mommaerts[10], Marika Mand[11], Guy Smagghe[12], Niklas Soderlund[13], Serdar Tuncer[14], Eve Veromann[15], Peter Witzgall[16]

[1]University of Helsinki, Finland, [2]Lower Saxony State Institute for Consumer Protection and Food Safety, Germany, [3]National Institute of Biology, Slovenia, [4]Swedish University of Agricultural Sciences, Sweden, [5]Ardahan University, Turkey, [6]Estonian University of Life Sciences, Estonia, [7]National Institute of Biology, Slovenia, [8]Agricultural and Environment Center Association, Italy, [9]University of Helskinki, Finland, [10]University of Ghent, Belgium, [11]Estonian University of Life Sciences, Estonia, [12]University of Ghent, Belgium, [13]Aland Islands Agricultural Research Station, Sweden, [14]Erzincan Agricultural Research Institute, Turkey, [15]Estonian University of Life Sciences, Estonia, [16]Swedish University of Agricultural Sciences, Sweden

BICOPOLL and BICOPOLL-NET connect 12 research units from 10 European countries and autonomous regions into a concerted effort to develop and bring into practice improved methods of biocontrol and pollination services, using strawberry as the case study. BICOPOLL partners will use bees to (i) precision deliver biocontrol agents to the flowers of the target crops to provide control of diseases, (ii) improve the pollination of horticultural crops. BICOPOLL will provide a pan-European case study on protecting strawberry from the grey mould. Additionally, we will improve the efficiency of the entomovector technology via innovative research on bee management, manipulation of bee behavior, and on the plant-pathogen-vector-antagonist-system, and will investigate possibilities of expanding the use of the concept into other berry and fruit growing systems. This is a highly innovative approach to solving some of the most difficult disease problems in berry and fruit production. The entomovector approach represents the only significant breakthrough in sight for improving plant protection in organic cropping systems and also conventional growers will benefit. We investigate, exploit, and support the natural ecological functions of biocontrol and pollination, and enhance these via innovative management. The entomovector technology contributes to improved resource use and efficiency in production, and enhances local biodiversity. The main target groups are organic and conventional strawberry growers, other berry and fruit growers, as well as beekeepers, to whom technology and knowledge transfer will be implemented during the project via direct contacts and by demonstration trials. The projects will cover three growing seasons during 2012?2014.

The use of companion planting for the management of the large white butterfly (*Pieris brassicae*) on white cabbage (*Brassicae oleracea* var capitata)

Gabriella Kovacs[1], Riina Kaasik[2], Anne Luik[3], Eve Veromann[4]

[1]Estonian University of Life Sciences, Estonia, [2]Estonian University of Life Sciences, Estonia, [3]Estonian University of Life Sciences, Estonia, [4]Estonian University of Life Sciences, Estonia

Large white butterfly (Lepidoptera: Pieridae) (LWB) is a noxious pest of Brassicaceous plants from Europe to Asia, their feeding on foliage can significantly reduce crop value. LWB has developed resistance against some insecticides therefore a new approach is needed to prevent widely spread insecticide resistant populations conjointly with negative effects of insecticides. LWB has several natural enemies; the most efficient ones are parasitoids. The larval endoparasitoid Cotesia glomerata can infest 90% of pests. As vegetation diversity and density can influence the abundance of pests and natural enemies, companion planting with different flowering plants were used to study their effect on LWB and its parasitoid, C. glomerata. The small scale experiment was carried out in Latin square design, companion plants used were Agastache J. Clayton ex Gronov, Lobularia maritima L., Anethum graveolens L., the control treatment was without companion plants. To estimate pest occurrence, all plants were inspected weekly to count all LWB larvae. For the estimation of parasitism percentage, 4th-5th instar caterpillars were collected from the field and incubated in the laboratory. Results indicated significant effect of companion plant species on the mean number of LWB larvae per plant. Parasitism level was 30% on A. graveolens, 23% on L. maritima, 21% on control and 17% on Agastache. The attractiveness of Lobularia maritima to LWB and C. glomerata reveal its suitability as a trap crop preventing pests from attacking the main crop and attracting parasitoids as their natural enemies to keep their abundance under the economical threshold level.

Keywords:*parasitism rate, biocontrol, Cotesia glomerata, Agastache J. Clayton ex Gronov, Lobularia maritima L., Anethum graveolens L.*

Wild hosts of spotted wing drosophila a new threat to berry crops in Florida, USA and elsewhere

James F. Price[1], Curtis A. Nagle[2]

[1]University of Florida, U.S.A., [2]University of Florida, U.S.A.

Florida, USA produced ca. 4,050 ha of strawberries and 1,500 ha of blueberries in 2011. Strawberries reach markets December through early March and blueberries March into May with little competition form other sources and command high prices. Drosophila suzukii (Diptera: Drosophilidae), an Asian pest of thin-skinned fruit, first was detected in the Americas in California fall 2008 and France, Spain, Italy and other European regions soon afterwards. Its first discovery in Florida came in August 2009. No commercially damaging infestations of berries have been reported there. More than 2 years trapping on the University of Florida Gulf Coast Research and Education Center (GCREC) beginning December 2009 detected flies only in summer, a commercial berry-free period there, when American black elderberry, Sambucus nigra subsp. canadensis fruited. However in January through March 2012 adults were captured there near fruiting strawberry fields but no damage occurred on the strawberries nor on the blueberry crop that followed March through April. Many local wild and cultivated landscape fruits have been identified available year round to sustain D. Suzukii. These include balsam apple (Momordica charantia), Barbados cherry (Malpighia emarginata), fig (Ficus carica), podocarpus (Podocarpus macrophyllis), fringe tree (Chionanthus virginicus), hog plum (Ximenia americana), orange jasmine (Murraya paniculata), Simpson's stopper (Myrcianthes fragrans), Florida privet (Forestiera segregata), mulberry (Morus rubra), and American black elderberry. Information has been developed to assist strawberry growers confronted with the fly.

Biological fitness and feeding behavior of imidacloprid-resistant and -susceptible brown planthopper, *Nilaparvata lugens* (Stal) on different resistant rice varieties

Jianming Chen[1], Li Chen[2], Yueping He[3], Juefeng Zhang[4]

[1]Zhejiang Academy of Agricultural Science, China, [2]Zhejiang Academy of Agricultural Science, China, [3]Zhejiang Academy of Agricultural Science, China, [4]Zhejiang Academy of Agricultural Science, China

The brown planthopper, Nilaparvata lugens is an economically important rice insect in China. Application of resistant varieties is the most economic method for controlling N. lugens populations, but chemical control is still a major method for suppressing the insect. The experiment indicated that on susceptible variety TN1, population number tendency index (PNTI) of imidacloprid-resistant and-susceptible N. lugens were 55.33 and 105.57, respectively; Relative fitness of resistant population to susceptible population was 0.5241. On resistant rice variety IR36, PNTI was 5.67 and 1.8, respectively, and relative fitness was 3.15. We found that PNTI of resistant and susceptible N. lugens at the 2nd, 3rd and 4th generations were 25.25 and 14.58, 14.52 and 11.85, 42.27 and 54.63, respectively. Relative fitness was 1.7318, 1.2253 and 0.7738, respectively. These indicated that imidacloprid-resistant N. lugens had stronger adaptability and survival advantage on resistant rice variety. Further experiment found seven classic waveforms of N. lugens on different rice varieties were recorded during feeding. On TN1, imidacloprid-resistant population had higher probe frequency, shorter probe time and longer phloem sap ingestion periods, but had no significant difference between two populations. On IR36, resistant population had lower probe frequency, shorter probe periods and longer xylem sap ingestion periods, but no found phloem sap ingestion waveform in two populations. With the increase of rearing generation, phloem sap ingestion periods of two populations further prolonged, especially imidacloprid-resistant population. The study will further elucidate resistant mechanism of rice and outbreak mechanism of N. lugens population.

Soil-borne insect pests have become increasingly important in crop production in DPR Korea (DPRK), with crop losses of 30% not uncommon. Control of these pests in DPRK has been hampered by the inability to implement preventive control techniques, such as crop rotation, or deploy effective plant protection products. The development of a locally viable biological control strategy, using entomopathogenic nematodes, has been proposed as a means to address this problem. Unfortunately, this strategy has been hindered by the limited local knowledge on the identification of key insect pests and their life-cycles, knowledge essential for the effective targeting of the biocontrol strategy. To address this lack of information field surveys were implemented in DPRK and soil insects collected for identification. In addition, reviews of available literature were carried out in DPRK. However, locally available information has proved limited. To gain more in-depth information on soil-borne insect pests which may be a problem in DPRK and their life-cycles, a literature survey was carried out focusing on the cold temperate and cold zones of East Asia (i.e. northeastern China, far southeast of Russia, Republic of Korea and DPRK) utilising the vast, non-English language source material. Information gathered to date will be presented and its use as a potential tool to support the development and implementation of a biocontrol strategy in DPRK discussed. This project is supported by the DG EuropeAid - Development & Cooperation (DCI-FOOD/2010/231-297) and the region-wide review by the Swiss National Science Foundation (IZK0Z3_140239 / 1).

Harmonic radar finders as insect monitoring devices

Gilles Boiteau[1], Charles Vincent[2], Francois Meloche[3], Tracy C. Leskey[4], L.-Y. Gui[5], Bruce G. Colpitts[6]

[1]Agriculture and Agri-Food Canada Fredericton, New Brunswick, Canada, [2]Agriculture and Agri-Food Canada Saint-Jean-sur-Richelieu, Quebec, Canada, [3]Agriculture and Agri-Food Canada Ottawa, Ontario, Canada, [4]USDA-ARS Appalachian Fruit Research Station, Kearneysville, West Virginia, U.S.A., [5]Yangtze University Hubei, China, [6]University of New Brunswick, Fredericton, New Brunswick, Canada

The study and monitoring of a wide range of organisms, including insects, are benefitting from the development of harmonic radar technology. The adoption of the technology has proceeded despite limited information on detection and recovery rates or on relative impact of the additional electronic tag load on insect mobility. The objective of this Canadian project has been to use a custom-designed portable harmonic radar to quantify the relative impact of those factors. Results carried out on three different insect pests (the plum curculio, the western corn rootworm and the Colorado potato beetle) validate the method as long as tags are adapted to each species and the radar scanning procedure adapted to the vegetative architecture.

Effect of sublethal insecticide exposure on individual variation in activity and prey capture in the jumping spider *Eris militaris* (Araneae: Salticidae)

Raphael Royaute[1], Chris M. Buddle[2], Charles Vincent[3]

[1]McGill University, Ste-Anne-de-Bellvue, Quebec, Canada, [2]McGill University, Ste-Anne-de-Bellevue, Quebec, Canada, [3]Agriculture and Agri-Food Canada, Saint-Jean-sur-Richelieu, Quebec, Canada

Studying the maintenance of individual variation in behaviour is becoming a major topic in ecology. This variation can be especially useful as a mean for species to cope with environmental changes. Agroecosystems are ideal to study such questions since they display wide ranges of human-induced disturbances (e.g., chemical spraying, habitat fragmentation). In this respect, chemical spraying is of particular interest since numerous pesticide compounds are known to induce behavioural modifications at sublethal doses. Yet, the effects of such exposure on the expression of individual variation are currently unknown. After exposing the jumping spider Eris militaris to dry insecticide residues for 24h, we determined how a sublethal dose of phosmet affected individual variation in activity and prey capture. All spiders were tested prior and after exposure to the insecticide. Repeatability of activity was highly affected by the insecticide treatment while prey capture was not. In addition, random regression analysis indicated that insecticide-exposed spiders had higher activity in the first minute of the test but their overall mean activity was lower compared to non-exposed spiders.

Leafhopper biodiversity in Canadian vineyards and feeding behavior of three *Erythroneura* species

Julien Saguez[1], Andy Hamilton[2], Chrystel Olivier[3], Charles Vincent[4], Jacques Lasnier[5], Brian Galka[6], Lorne Stobbs[7], Tom Lowery[8], Philippe Giordanengo[9]

[1]Agriculture and Agri-Food Canada Saint-Jean-sur-Richelieu, Quebec, Canada, [2]Agriculture and Agri-Food Canada, Ottawa, Ontario, Canada, [3]Agriculture and Agri-Food Canada, Saskatoon, Saskatchewan, Canada, [4]Agriculture and Agri-Food Canada, Saint-Jean-sur-Richelieu, Quebec, Canada, [5]Co-Lab R&D, Division of Ag-Cord Inc., Granby, Quebec, Canada, [6]Agriculture and Agri-Food Canada, Saskatoon, Saskatchewan, Canada, [7]Agriculture and Agri-Food Canada, Vineland, Ontario, Canada, [8]Agriculture and Agri-Food Canada, Summerland, British Columbia, Canada, [9]Universite de Picardie Jules Verne, Amiens, France

Leafhoppers (Cicadellidae) are pests of many temperate crops, including grapevines. Ca. 18,000 specimens were collected in 80 commercial vineyards located in the provinces of British Columbia, Ontario and Quebec (Canada). We identified 54 genera and at least 110 different species associated with vineyards, among which 22 were predominant and represented more than 91% of leafhopper specimens. We observed variations in species composition across the years and the provinces. Erythroneura species are the most abundant leafhoppers collected in Canadian vineyards. Due to the ability of leafhoppers to transmit phytoplasmas on grapevines during plant feeding, we studied the behavior of three Erythroneura species by electropenetrography in order to identify the damage and fed plant tissues. Our results indicated that Erythroneura species are essentially mesophyll feeders. As phytoplasmas are generally considered to be restricted to phloem sap, this brings into question the Erythroneura species ability to vector phytoplasmas in grapevine.

The study on the protein bait of *Bactrocera dorsalis* (Diptera: Tephritidae)

Wenjing Zhang[1], Hongyu Zhang[2]

[1]College of Plant Science and Technology, Huazhong Agricutural University, China, [2]College of Plant Science and Technology, Huazhong Agricutural University, China

The oriental fruit fly, Bactrocera dorsalis, is one of the most important quarantine pests in Asian countries. It can feed on up to 250 different types of fruits and vegetables, causing severe ecnomic loss. Currently, there is no ideal control program. To finally effective control on these pests, we have developed a new bait based on protein X exhibiting very significant luring effect to both females and males with luring rate of 39.33%. In lab bioassays, two different lure baits both based on protein X were used. The lure rate of both baits reached peak at 24 h, with the one composed of 5g brown sugar: 5g protein X: 3g ammonium acetate: 50mL water was 55%, while the other composed of 5g brown sugar:5g protein X:10 mL white vinegar was 43%. The latter was then applied in the field bioassays and showed the most effective trapping activity on the third day. Adding 0.5% methyleugenol and 0.5% dichlorvos EC into the protein bait increased the trapping activity and the poisonous effect.

Study on non-chemical control techniques of *Thrips flavidulus* (Thysanoptera: Thripidae)

Haifeng Yao[1], Fahui Yu[2], Hongyu Zhang[3]

[1]College of Plant Science and Technology, Huazhong Agricutural University, China, [2]College of Plant Science and Technology, Huazhong Agricutural University, China, [3]College of Plant Science and Technology, Huazhong Agricutural University, China

Thrips flavidulus has caused great damages to citrus, peach and banana etc. orchards in China. In this study, the functional and numerical responses for the adults of the predatory mites Amblyseius cucumeris, Amblyseius barkeri and Euseius nicholsi on Thrips flavidulus first-instar larvae were studied to evaluate their predation ability on T. flavidulus. The results showed that the functional response of adult A. cucumeris, A. barkeri and E. nicholsi could be described by the Holling II functional response type. The results suggested that predation ability of A. cucumeris was strongest to T. flavidulus among three predatory mites and prey density significantly influence reproductive ability of A. cucumeris and E. nicholsi, but not A. barkeri. Among 10 types of colors sticky cards named yellow、blue、deep-blue、white、red、green、purple、gray and pink in citrus orchards, the thrips had the strongest preference to the blue sticky card and the deep-blue sticky card, on which the thrip numbers existed a significant difference from those on the other eight colors sticky cards ($p<0.01$). The trapping techniques of blue sticky card were discussed. Effect of 16 different plant volatile compounds on the behavior of adult female thrips was tested with a Y-tube olfactometer. The results showed that T. flavidulus were attracted by the compound of benzenoids and monoterpenes isoprenoids, and same compound at different concentration has different action. The compound A and E have the significant attraction to thrips at concentration 10% and 1%.

Behavioral response of the egg-larval parasitoid Ascogaster reticulata to tea leaves treated with host eggs or other host materials

Narisara Piyasaengthong[1], Yooichi Kainoh[2]

[1]*University of Tsukuba, Japan,* [2]*University of Tsukuba, Japan*

The relationship between herbivore-induced plants and parasitoids receives attention recently. Chemicals released by plants when they are attacked by herbivores are useful for natural enemies to find their hosts in tritrophic interactions. An interesting phenomenon is that some plant species can respond to the first step in a herbivore attack of laying eggs on host plants. Ascogaster reticulata Watanabe (Hymenoptera: Braconidae) is a solitary egg-larval endoparasitoid of several tortricid species, including Adoxophyes honmai. Host searching behavior(s) of A. reticulata for hosts on tea leaves can be stimulated by cues produced from tea leaves not only infested by A. honmai egg mass deposition without visually recognizable damage but also leaves treated with A. honmai reproductive organs. Egg masses of female A. honmai induced tea leaves to arrest A. reticulata to spend significantly more time on treated leaves than control leaves. Moreover, elicitors in the mated female reproductive organ of A. honmai also induced tea leaves to produce cues that arrested parasitoids 24-48 hr after treatment of the leaves. In contrast, the total time parasitoids spent on infested tea leaves at 1 hour was not significantly different when compared with the control. The concentration of the female reproductive organ homogenate was important for inducing tea leaves to produce cues because the time spent by parasitoids for searching on tea leaves treated with the original concentration(reproductive organ+10µl Ringer's solution) was significantly longer than lower concentrations. The specificity of the elicitors is discussed based on these results.

Pyrethroid resistance in melon thrips, *Thrips palmi* Karny

Wen Xue Bao[1], Shoji Sonoda[2]

[1]*Institute of Plant Science and Resources, Okayama University, Japan,* [2]*Okayama University, Japan*

The melon thrip, Thrips palmi Karny, is among the most destructive pests of vegetables in western Japan because of its development of insecticide resistance. To examine its resistance mechanisms against a pyrethroid, cypermethrin, we determined partial nucleotide sequences of the sodium channel gene and compared the deduced amino acid sequences among 11 strains of T. palmi showing different levels of resistance. All the 11 strains had an amino acid substitution T929I alone. The synergist, pyperonyl butoxide, showed synergistic effects of the susceptibility to cypermethrin in the most resistant and least resistant strains. There was no significant difference in enzymatic activities of carboxyl esterase and glutathione-S-transferase between both strains. These results suggest that both reduced sensitivity of the sodium channel caused by T929I and CYP450-mediated detoxification are involved in the pyrethroid resistance of T. palmi.

Management of strawberry blossom weevil and European tarnished plant bug in organic strawberry and raspberry using semiochemical traps

Atle Wibe[1], Ilze Apenite[2], Catherine Baroffio[3], Anna-Karin Borg-Karlson[4], Jerry Cross[5], David Hall[6], Lene Sigsgaard[7], Nina Trandem[8]

[1]Bioforsk - Norwegian Institute for Agricultural and Environmental Research, Norway, [2]Latvian Plant Protection Research Centre, Latvia, [3]Agroscope Changins-Wadenswil ACW, Switzerland, [4]KTH-Royal Institute of Technology, Sweden, [5]EMR-East Malling Research, United Kingdom, [6]NRI-Natural Resources Institute, United Kingdom, [7]University of Copenhagen, Denmark, [8]Bioforsk - Norwegian Institute for Agricultural and Environmental Research, Norway

The strawberry blossom weevil (Anthonomus rubi) and the European tarnished plant bug (Lygus rugulipennis) cause large (10 - >80%) losses in yield and quality in organically grown berries. A consortium with 6 European countries has been created to work on the management of those pests. The pheromones of A. rubi and L. rugulipennis have been characterized in England by NRI/EMR. For the attraction of A. rubi the importance of host plant volatiles in combination with the pheromones has also been documented. The natural semiochemical mechanisms of sexual attraction and host plant finding of A. rubi and L. rugulipennis will be further studied and exploited to develop effective semiochemical traps for their management through mass trapping. Attractive lures for these two species will then be combined into a single multitrap with the aim of managing two pests simultaneously in each crop. This will be one of the first approaches to pest management of non-lepidopteran insect pests of horticultural crops using semiochemicals in the EU, and probably the first to target multiple species from different insect orders. The project will be organized in the following work packages; 1) Chemical analysis of plant volatiles, 2) Pest insects in strawberry, 3) Pest insects in raspberry and 4) Trap design and lure development. The authors gratefully acknowledge the financial support for this project provided by the CORE Organic II Funding Bodies, being partners of the FP7 ERA-Net project, CORE Organic II (Coordination of European Transnational Research in Organic Food and Farming systems, project no. 249667).

Mating disruption of *Planococcus kraunhiae* (Kuwana) (Hemiptera: Pseudococcidae) with its sex pheromone in Japanese persimmon orchards

Yutaka Narai[1], Nobuo Sawamura[2], Rikiya Sasaki[3], Jun Tabata[4], Mayumi Teshiba[5]

[1]Shimane Agricultural Technology Center, Japan, [2]Shimane Agricultural Technology Center, Japan, [3]Fuji Flavor Co. Ltd., Japan, [4]National Institute for Agro-Environmental Sciences, Japan, [5]Fukuoka Agricultural Research Center, Japan

We demonstrated the control of the Japanese mealybug Planococcus kraunhiae (Kuwana) by the mating disruption with sex pheromone from 2008 to 2010 in Japanese persimmon orchards. A grey rubber septum (8mm outside diameter, West Pharmaceutical Co., Singapore) impregnated with three milligrams of the pheromone was used a dispenser. Dispensers were set in orchards at the end of April in each year. The treated quantity of the pheromone was 1g/a (2008-2010) and 0.1g/a (2009). The treated area was 2.3a to 4a. As a result, number of caught males to a pheromone trap in the 1g/a treated place was far fewer than numbers of them in the no-pheromone place through the persimmon growing season (April to October) in each year. The rate of ovipositing females, which were enveloped in a net with diet and exposed in each place during several days before copulation, in the 1g/a treated place were almost zero through the persimmon growing season in each year. The infested fruit rate in the 1g/a treated place was lower than the rate in the no-pheromone place at any time in each year. In the 0.1g/a treated place, the above three parameters were occasionally worse than them in the no-pheromone place after September. We thought that the mating disruption in the 0.1g/a treated place worked until the end of June at least. From the above, mating disruption of Planococcus kraunhiae with the 1g/a sex pheromone was successful throughout the persimmon growing season.

Population genetics of *Bactrocera dorsalis* s.s. and *B. papayae* across Thai-Malay Peninsula

Nidchaya Aketarawong[1], Siriwan Isasawin[2], Sujinda Thanaphum[3]

[1]Mahidol University, Thailand, [2]Faculty of Science, Mahidol University, Thailand, [3]Faculty of Science, Mahidol University, Thailand

Sterile Insect Technique (SIT) is an environmentally-friendly based method to control insect pest. This method is relied on mating between released sterile and wild insects resulting in a reducing of pest population size from generation to generation. However, some key pests are members of species complex and exist in the same area. If genetic isolation exists between members of complex, use of SIT to control one species might not effectively control another members. Otherwise, if genetic exchange is detected, releasing sterile insects of only one species is possible to suppress other members. In this study, we explore the population genetics of two invasive fruit fly pests, Bactrocera dorsalis s.s. and B. papayae, members of the Bactrocera dorsalis species complex. We have analyzed the data of 12 microsatellite loci (i.e., seven originated from B. dorsalis s.s. and the rest loci originated from B. papayae) from 17 populations sampled in sympatric/ allopatric areas across Thai-Malay Peninsula. The preliminary data showed that genetic variation of two species was similar. In addition, genetic exchange between two species was observed in some locations, both sympatric and allopatric areas. This result was also congruent with no significant correlation between genetic and geographic distances. Population genetic data implies potential use of one SIT to control two species in some areas of Thai-Malay Peninsula.

The SLU Centre for Biological Control: Generating new knowledge on sustainable application of biological control

Margareta Hokeberg[1], Hanna Friberg[2], Sebastian Hakansson[3], Mattias Jonsson[4], Ingvar Sundh[5]

[1]Swedish University of Agricultural Sciences, Sweden, [2]Swedish University of Agricultural Sciences, Sweden, [3]Swedish University of Agricultural Sciences, Sweden, [4]Swedish University of Agricultural Sciences, Sweden, [5]Swedish University of Agricultural Sciences, Sweden

At the new Centre for Biological Control (CBC) we conduct fundamental and applied research on biological control (i.e. the use of living organisms to control populations of harmful organisms), which aims to strengthen the knowledge base and facilitate the development and implementation of new biocontrol products and approaches. The centre works with augmentation, conservation and classical approaches, with utilization of both microorganisms and invertebrate animals. Close cooperation with stakeholders, such as growers, industry, authorities and organisations is an integral part of CBC activities. The research at the centre is lead by five scientists: Margareta Hokeberg's research area concerns bacteria for biological control. Her current interest is how to use combinations of different biocontrol agents and combining biocontrol with other control measures for sustainable disease control. She is also the CBC director. Hanna Friberg works on fungi in biocontrol. She has focused on plant pathogenic fungi causing disease in agricultural crops - how they can be managed without chemical control and how different cultural practices influence their abundance and activity. Sebastian Hakansson's areas of interest are that of long-term stabilization of microorganisms and life in the dry state, anhydrobiosis. Mattias Jonsson is specialised in insects and arachnids for biocontrol. His research is mainly focused on conservation biological control of invertebrate pests in agroecosystems. Ingvar Sundh works with issues related to safety and regulatory measures. He focuses on strategies to determine that a biocontrol agent has no unacceptable adverse effects in humans, non-target organisms in agriculture and forestry, and the general environment.

Two weevil species, Cylas formicarius and Euscepes postfasciatus, are world-wide major pests of sweet potato. In Okinawa, Japan, we are challenging to eradicate them by the sterile insect technique. To release high proportion of sterile target pests into a field population, a mass-rearing method with an artificial diet is a basic requirement. Although the artificial diet and rearing method for E. postfasciatus had been established and executed in a mass-production facility, the ones for C. formicarius have not been established yet. This mainly results from lack of 1) suitable substrate inducing female oviposition and 2) a method of collecting their eggs that are brittle relative to E. postfasciatus eggs. In the present study, we struggled with these problems. Firstly, we prepared several artificial diets chiefly consisting of sweet potato powder and agar, and reared C. formicarius gravid females individually during 35 days. They survived with these diets only and consistently laid eggs (0.14 egg/d). This is the first report of C. formicarius oviposition on an artificial diet. Secondly, we examined change in egg-shell hardness after oviposition to seek timing of collecting the egg without damage. The egg dramatically hardened as developing and eventually became over threefold hard as E. postfasciatus eggs, which can be collected by simple methods, suggesting that 3 days or later old C. formicarius eggs should be collectable. Thus, we overcame the two problems on the first step in exploring the artificial diet for C. formicarius. We will discuss further possible difficulties in establishing the mass-production procedure.

Insecticidal effect of Jatropha curcas oil on the main insect pests associated with cowpeas (*Vigna unguiculata*) in Niger

Zakari Abdoul Habou[1], Frederic Francis[2], Toudou Adam[3], Guy Mergeai[4], Eric Haubruge[5], Francois Verheggen[6]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]Abdou Moumouni University of Niamey, BP 10960, Niger, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium, [6]University of Liege - Gembloux Agro-Bio Tech, Belgium

Application of J. curcas oil at 5% and 7.5% concentrations significantly reduce the level of attack by aphids (Aphis craccivora) by 10 and 50% respectively compared to the control. Firstly, a 50% and 75% fall in the number of thrips (Megalurothrips sjostedti) and bugs (Anoplocnemis curvipes), respectively, can be observed under the same conditions. This treatment allowed to greatly increase yields compared to the untreated parcel. Secondly, we compared the insecticidal activity of two batches of oil conserved during 70 days in plastic containers, one exposed to light and the other kept in the dark. The insecticidal activity of 5,10 and 15% of J. curcas oil conserved during 70 days was evaluated in a field test on the main devastating pests of Cowpea (Vigna unguiculata ((L.) Walp) . There was no significant difference in insecticidal activity between the two modes of conservation of J. curcas oil with various concentrations. The concentration of 10% in all modes on conservation allowed a reduction of devastating, more than 80% of thrips, aphids, bug and 75% of Jassides compared to the untreated parcel. The concentrations of 15% give an insecticidal effect comparable to (deltamethrine) but induce symptoms of phyto- toxicity on the leaves of cowpea.

Application of semiochemical releasers and intercropping to control aphid and related virus in East China

Emilie Bosquee[1], Thomas Lopes[2], Damien Polo Lozano[3], Sophie Vandermoten[4], Ju Lian Chen[5], Cheng DengFa[6], Liu Yong[7], Eric Haubruge[8], Frederic Francis[9]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]Chinese Academy of Agricultural Sciences, China, [6]Chinese Academy of Agricultural Sciences, China, [7]Shandong Agricultural University, China, [8]University of Liege - Gembloux Agro-Bio Tech, Belgium, [9]University of Liege - Gembloux Agro-Bio Tech, Belgium

Nowadays, the control of aphids - well known virus vectors, lies on the use of synthetic insecticides. The chemicals' harmful effects on the environment and on human health led to some research aiming at the development of new alternative methods that would be efficient for producers. Within this context of biological control against aphids and their virus transmission, semiochemical substances (pheromone and allelochemicals) and the intercropping are strategies increasingly studied. The properties of the semiochemical moleculles were used to implement 'push-pull' techniques to repel pests and attract beneficial insects. Intercropping was applied as an attractive strategy for managing pests and viruses through the release of allelochemicals or by associating plants in intercropping. In this study, three semiochemical substances namely (E)-β-farnesene (EBF), cis-3-hexenyl acetate, garlic extract and peas intercropping were separately tested. Yellow traps were used and complemented by visual observation in the potato field plots corresponding to each kind of treatments. The evaluation of the abundance and diversity of aphids was performed weekly by collecting insects in fields and indentifying in the laboratory. The presence of viruses (Potato virus Y (PVY) and Potato Leaf Roll Virus (PLRV)) and the proportion of infected plants in each plot were evaluated by enzyme-linked immunosorbent assays (ELISA). Between the different treatments, the cultural association presented higher repulsive effects than the released semiochemical moleculles. Investigated strategies to control aphid and related virus were discussed in terms of efficacy and perspectives of application in larger scale for sustainable crop production.

Mating disruption for control of codling moth, *Cydia pomonella*, in commercial apple orchards in Quebec, Canada

Daniel Cormier[1], Francine Pelletier[2]

[1]Research and Development Institute for the Agri-Environment, Canada, [2]Research and Development Institute for the Agri-Environment, Canada

The codling moth, Cydia pomonella L. is a key pest of many fruits and nuts throughout the world. In the last 15 years, damage from this pest has been continuously increasing in all major apple regions of Quebec resulting in increasing number of annual sprays of insecticide needed for adequate control. In order to reduce the environmental impact and the risks for development of insecticide resistance, a decrease in pesticide use is desirable. Mating disruption (MD) has shown promise as a preventive tool to manage codling moth populations in many parts of the world. The objective of this project was to evaluate the efficacy of Isomate® CM-OFM TT for the management of codling moth under Quebec conditions in three apple orchards with different codling moth pressure. In each orchard, plot with MD (> 4 ha) was paired with a control plot treated with conventional insecticides alone. In order to reduce pest populations to levels more easily manageable, the standard spray programs were maintained to supplement control for the first year in MD-treated plots. Under moderate and high codling moth density, respectively 159 and 218 cumulative moth captures, four insecticide sprays were required to control codling moth and adequate control was achieved in both plots, with and without mating disruption (< 1,0 %). Under low codling moth density (53 captures), no insecticide treatment was done to control codling moth but high levels of damage (6,0 %) was observed in plot without MD while damage was near zero in MD-treated plot.

Phenotypic and genetic diversity of rice varieties and relation to attack of *Diatraea saccharalis*

Jose Alexandre F. Barrigossi[1], Jacqueline Barbosa Nascimento[2], Paulo Marcal Fernandes[3], Tereza Cristina de Oliveira Borba[4], Raquel Neves de Mello[5], Jose Francisco da Silva Martins[6]

[1]Embrapa Arroz e Feiao, Brazil, [2]Universidade Federal de Goias, Brazil, [3]Universidade Federal de Goias, Brazil, [4]Embrapa Arroz e Feijao, Brazil, [5]Embrapa Rice and Beans, Brazil, [6]Embrapa, Brazil

The response of 34 accessions of rice (Oryza sativa L.) to infestation of stem-borer (Diatraea saccharalis Fabr.) was determined and characterized genotypically and phenotypically. Susceptibility to D. saccharalis was determined infesting plants with neonate stalk borer larvae (20 larvae/hill). The experimental design was a randomized complete block with four replications. Each plot was represented by a clump of ten plants. At the time of infestations plants were confined in cylinders (measuring 0,2m in high and 0,25m in diameter). Thirty five days after infestations plants were cut at the soil level, and brought to laboratory. All tillers were carefully examined looking for sign of attack, and presence of larvae. External and internal diameters of the stem and weight the surviving larva also were determined. For molecular analysis of rice varieties, 24 microsatellite markers were used. Highly significant positive correlations were recorded between survivorship of larvae and external and internal diameters of the stem. Molecular analysis of the rice genotypes in which 24 SSR loci were used, revealed a total of 243 polymorphic alleles with an average of 10.2 alleles per locus. Cluster analysis performed with genotypic data showed a significant genetic divergence among the genotypes of rice and a strait relationship between the phenotypic data that differentiated the genotypes more resistant to D. saccharalis. This study showed that there is a complete correspondence between the groups formed by these clustering methods under the two aspects analyzed (phenotypic and molecular).

Pathogenicity test of the fungus *Aspergillus clavatus* on aphid *Acyrthosiphon pisum* (Aphididae)

Fawrou Seye[1], Thomas Bawin[2], Franck Delvigne[3], Frederic Francis[4]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium

Pea aphid is a pest of many cultivated and wild plants, but also a vector of several viral diseases. To control this pest, the most widely used methods are physical, chemical and more recently an integrated approch that includes biological control. With the use of pathogenic agents against insects, the use of entomopathogenic fungi is one of the most promising. The present study demonstrated the possibility of using an entomopathogenic fungus Aspergillus clavatus against aphids. In laboratory conditions (8/16 photoperiod, average temperature 25oC), the insects were in contact with different concentrations ranging from 102 to 10 4 spores/cm2 deposited on filter paper in Petri dishes, or applied directly to young plants with doses ranging from 104 to 106 spores / ml. In 24 hours, mortality was 0 to 31.5% in Petri dishes. For treatment plants, the cumulative mortality in 5 days was 55 to 79%. Microscopic observations showed that the aphids were infected by contact and fungus has a mycosis effect. From these preliminary results, investigations should be made to study the action of the fungus on the reproduction of aphids. Therefore, A. clavatus could be introduced along with other fungi found in the literature as a biological control agent against aphids.

Damage levels of two stink bugs (Heteroptera: Pentatomidae) that feed on rice stems in Brazil

Tavvs Micael Alves[1], Jose Alexandre F. Barrigossi[2], Daniel Ferreira Caixeta[3], Henrique Matias R. Silva[4]

[1]Universidade Federal de Goias, Brazil, [2]Embrapa Arroz e Feijao, Brazil, [3]Universidade Estadual Paulista, Brazil, [4]Universidade Federal de Goias, Goiania, GO, Brazil

Tibraca limbativentris and Glyphepomis spinosa are the only stink bugs that have been feeding on rice stem in Brazil. Field and greenhouse studies were conducted from 2007 to 2012 in Santo Antonio de Goias, GO, Brazil, to determine rice yield-loss due to these two species of stink bugs. A randomized block design was used with four replications. Infestations with T. limbativentris were made with different insect densities at the beginning tillering, maximum tillering, and booting. The yield was regressed in function of number of stink bugs/unit of area, and the slope of the linear regression was used as the DI (yield loss/insect density) variable in economic injury level (EIL) calculations. In addition, experiments were conducted with one couple of G. spinosa per pot with rice plants. These adults remained on plants since infestation until the removal in the final of feeding time stipulated by the nine treatments. Injury of both stink bugs negatively affected most of yield components; however, damage imposed at vegetative phase was more severe than at the reproductive phase. Overall, EILs for T. limbativentris depended on plant stage: 0.5 adult/m2 in the maximum tillering and 1.0 adult/m2 in the booting. In conclusion, G. spinosa can reduce the rice yield more than T. limbativentris.

Assessment of synthetic chemicals for disruption of *Rhynchophorus ferrugineus* attraction in an urban environment

Salvatore Guarino[1], Ezio Peri[2], Paolo Lo Bue[3], Mari Pia Germana[4], Stefano Colazza[5], Leonid Anshelevich[6], Victoria Soroker[7]
[1]University of Palermo, Italy, [2]university of palermo, Italy, [3]University of Palermo, Italy, [4]University of Palermo, Italy, [5]university of palermo, Italy, [6]Volcani Center, Bet Dagan, Israel, [7]Volcani Center, Bet Dagan, Israel

The red palm weevil (RPW), Rhynchophorus ferrugineus Olivier (Coleoptera, Curculionidae), is currently one of the most severe pests of Canary palms in urban areas of Mediterranean countries and date palms in cultivated areas of the Middle East. RPW aggregation pheromone can be implemented for both monitoring and mass trapping however risks of RPW 'spillover' onto palms is of great concern. Aim of this work was to discover repellent semiochemicals for RPW population management in urban environments. For this purpose we conducted electroantennographic (EAG) screenings of 17 commercially available synthetic compounds, representing three groups of plant volatiles (isoprenoids, phenyl propanoid derivatives and fatty acid derivatives) known for their repellent effects toward insects. EAG bioassays results showed positive dose-dependent responses to 13 of the 17 synthetic chemicals on RPW antennae of both sexes. These tests were followed by trap-based screenings of EAG-active menthone, α-pinene methyl salicylate, 1-octen-3-ol and citronellol, singly and in combination, under urban conditions. These trapping experiments were conducted in the city of Palermo, Italy during 2010, 2011 and 2012 to test the behavioural effect on the RPW adults. Experiments were carried out by placing the tested chemicals inside the pheromone baited traps and assessing a possible reduction in the adult captures. In particular were tested: in 2010 α-pinene and methyl salicylate, in 2011 α-pinene and menthone, in 2012 α-pinene, 1-octen-3-ol and citronellol. The results of trap tests showed that some of the compound tested significantly reduce the number of RPW captures in the traps.

Comparison of aphidofauna in Belgium and Mali and potential impact on potato virus dispersion

Almouner A. Yattara[1], Amadou K. Coulibaly[2], Claude Bragard[3], Sophie Vandermoten[4], Eric Haubruge[5], Frederic Francis[6]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]2 Biology laboratory of arthropoda and IPM (IPR/IFRA), Belgium, [3]Catholic University of Louvain, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium, [6]University of Liege - Gembloux Agro-Bio Tech, Belgium

Climate changes focusing on global warming and the consequences on insect distribution are often cited mainly for exotic pests Here, studies were carried out during three years (from 2009 to 2011) in potato fields, to determine the abundance and diversity of aphids (Homoptera, Aphididae), and potential impact of potato viruses dispersion both in Europe, particularly in Belgium, and in west Africa, in Mali. Aphid populations were recorded by visual observations on potato leaves and using yellow water-pan traps. The monitoring was made weekly in different locations. The identification of aphid species was operated in laboratory, Most of the identified species were not potato colonizers. Main aphid transmitted virus, namely Potato virus Y (PVY) and Potato leaf roll virus (PLRV) were assessed by enzyme-linked immunosorbent assays (ELISA) technique. More than 30 species of aphids were identified in Belgium, while 15 species in Mali, of which seven are common to both countries (Aphis fabae, Brevicoryne brassicae, Lypaphis erysimi, Myzus persicae, Rhopalosiphum insertum, Rhopalosiphum padi and Tetraneura sp.) Major aphid species transmiting potato viruses were Myzus persicae, Aphis gossypii(from Mali), Macrosiphum euphorbiae and Aulacorthum solani (from Belgium). PVY and PLRV were variably occurring in Mali and Belgium, PVY being the most abundant. These resluts were performed as a step to monitor and apply some suitable strategies to manage potato aphids and related viruses.

Preliminary study of hydroxymethylfurfural (HMF) presence in syrup to feed bees in Belgium

Lara Zirbes[1], Bach Kim Nguyen[2], Sophie Vandermoten[3], Dirk C de Graaf[4], Bruno De Meulenaer[5], Wim Reybroeck[6], Claude Saegerman[7], Eric Haubruge[8]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]Gent University, Belgium, [5]Gent University, Belgium, [6]Institute for Agricultural and Fisheries Research, Belgium, [7]University of Liege, Belgium, [8]University of Liege - Gembloux Agro-Bio Tech, Belgium

In 2009-2010 in Belgium, abnormal losses of colonies of bees were observed. Later analyses showed that some of these colonies had been fed during winter with syrup of inverted beet sugar which presented a high concentration of hydroxymethylfurfural (HMF). Several studies confirmed a toxic effect of the HMF on the health of the bee. At the moment, the absence of toxicological data of reference does not allow to establish a limit of definitive action susceptible to stop the problem. Preliminary study on HMF in syrups (for wintering or stimulation) to feed bees has been realised in order to point out HMF formation. We have compared several home-made syrups and commercial syrup often used by beekeepers in Belgium. Several measurements have been performed on all syrups stored at three different temperatures: pH, sugars composition, and HMF content. The results showed that most of the analyzed syrups contained mainly saccharose, had pH around 7 and a very little HMF content (< 5ppm). More interesting, commercial syrup and home-made syrup of water and saccharose mixed with pollen mainly contained fructose and glucose, and had acid pH around 3.5. Thus they contained the highest HMF content as well. These results highlighted the importance to standardize the production of syrup for beekeepers and especially for commercial producers that use directly fructose and glucose in their mixture.

Invasive exotic plant species in the Southern Appalachians (USA): Potential targets for biological control

Jerome F. Grant[1], Gregory J. Wiggins[2], Paris L. Lambdin[3]

[1]University of Tennessee, U.S.A., [2]University of Tennessee, USA, U.S.A., [3]University of Tennessee, U.S.A.

Invasive exotic plant species pose a risk to agriculture, forestry, natural areas, and urban habitats throughout the world. Numerous species are well established in the southern Appalachians in the United States, where they are serious economical and environmental concerns. The threat of some invasive plant species, such as kudzu (Pueraria montana var. lobata), multiflora rose (Rosa multiflora), and musk thistle (Carduus nutans), is well documented, and these species are well recognized by growers and landowners. Management programs, primarily focused on chemical, mechanical and cultural controls, have been developed to limit the spread of these exotic plant species, and biological control is a major component of integrated pest management of musk thistle. However, the threat of other species, such as Canada thistle (Cirsium arvense), purple loosestrife (Lythrum salicaria), and spotted knapweed (Centaurea stoebe L. subsp. micranthos), in the southern Appalachians is not as well known, and growers and landowners are not as familiar with these exotic species. In most cases, distribution of these invasive plant species has not been clearly defined. In addition, the diversity of native and exotic insect herbivores that utilize many of these introduced plant species has not been investigated. Biological control will be explored as a management tactic against selected exotic weeds based upon the 'best fit' for the area's climate and geography. This poster details selected invasive exotic plant species established in the southern Appalachians and examines the potential for the integration of biological control into pest management programs directed against them.

Status of the codling moth and the oriental fruit moth populations in apple orchards of Quebec, Canada

Daniel Cormier[1], Caroline Provost[2], Franz Vanoosthuyse[3], Gerald Chouinard[4]

[1]Research and Development Institute for the Agri-Environment, Canada, [2]Centre de Recherche Agroalimentaire de Mirabel, Canada, [3]Research and Development Institute for the Agri-Environment, Canada, [4]Research and Development Institute for the Agri-Environment, Canada

In the last decade, population densities of the codling moth, Cydia pomonella (L.), have increased in most apple growing areas of Quebec, Canada. A second species of internal Lepidoptera, the oriental fruit moth, Grapholita molesta (Busck), has been observed for the first time in 2002 in the same area. Catches records from this time indicate that the distribution areas of these two apple pests are gradually expanding. Beside insect resistance and climate changes, we hypothesized that this growth could originate from (1) an increase in the numbers of weakly managed apple orchards including abandoned orchards, and (2) an increase of imported apples. To determine which of these two potential infestation sources could be involved, moth catches were followed weekly from the beginning of the adult flight to harvest, during two years, in the three most important apple growing areas of Quebec, Canada. Trap counts were compared from (1) weakly managed apple orchards; (2) monitored apple orchards; (3) unmonitored apple orchards and (4) storage sites of imported bins. Adult catches from these sites did not indicate a clear pattern in terms of infestation sources of these two internal Lepidoptera. In each apple region, the lowest number of codling moth and oriental fruit moth adult catches were observed from storage sites of imported bins. However, the rejection of our second hypothesis should be confirmed from the observation of individually wooded bins in order to detect newly emerged adults from overwintering cocoons.

Prevalence of phytoplasma diseases in Canadian vineyards

Chrystel Olivier[1], Julien Saguez[2], Brian Galka[3], Lorne Stobbs[4], Tom Lowery[5], Charles Vincent[6]

[1]Agriculture and Agri-Food Canada, Canada, [2]Agriculture and Agri-Food Canada, Canada, [3]Agriculture and Agri-Food Canada, Canada, [4]Agriculture and Agri-Food Canada, Canada, [5]Agriculture and Agri-Food Canada, Canada, [6]Agriculture and Agri-Food Canada, Canada

Leafhoppers are pests that can affect grapevines, notably by transmitting phytoplasmas. A survey of phytoplasma diseases was conducted in Canadian vineyards between 2006 and 2011. Leafhoppers and plants were sampled each year and phytoplasmas were identified using PCR and DNA sequencing. Phytoplasma DNA was detected in 40 cicadellid species. Several grapevine cultivars were also detected phytoplasma-positive. Disease incidence varied with the year, cultivar and province. Phytoplasma strains belonging to the Aster Yellow and Ash Yellow groups were detected.

Insights into the potential of classical biological control in a changing climate

Owen Olfert[1], Tim Haye[2], Ross Weiss[3], Ulrich Kulmann[4]

[1]AAFC, Canada, [2]CABI, Switzerland, [3]AAFC, Canada, [4]CABI, Switzerland

Climate is the dominant force determining the distribution and abundance of most insects. There has been considerable concern in recent years about climatic warming caused by human activities and the effects of these changes on agriculture in North America. Warming conditions are likely to affect insect populations, both pest and beneficial species. Given that the magnitude of predicted temperature change associated with climate change is beyond the historical experience of modern agriculture, bioclimate models offer insights into the impacts of climate change and the issues facing development of future IPM strategies. The objective of the study was to develop bioclimatic models to predict potential range and relative abundance of a parasitoid P. digoneutis and its host Lygus spp. and to use the models to develop a better understanding of how climate affects the status of biological control efforts to manage Lygus populations in North America. The results of the study showed that range and distribution of the parasitoid and its host were positively and negatively affected based on specific combinations of temperature and precipitation. Sensitivity analysis indicated that P. digoneutis will continue to be successful even with the warmer temperatures predicted in future climates. In conclusion, the study provided insights that offered increased success for establishment of a classical biological control agent for the management of an insect pest. Adaptation strategies, such as classical biological control, can be employed to mitigate the effects of a changing climate.

Plant physiological disruption preceding hopperburn by a leafhopper

William O. Lamp[1], Bridget DeLay[2]

[1]University of Maryland, U.S.A., [2]University of Maryland, U.S.A.

Hopperburn is one of the defining symptoms of plant injury by a number of hemipteran pest species. Research on potato leafhopper, Empoasca fabae, has demonstrated physiological disruption of gas exchange processes (e.g., photosynthesis, transpiration) well before the appearance of hopperburn symptoms on their host plants, notably alfalfa, Medicago sativa. Here, we report on a series of experiments that demonstrate disruption of gas exchange processes and that help to elucidate the mechanism of injury. First, significant declines in photosynthesis and transpiration occur within 12 hours of the initiation of feeding, reaching an average decline of 30% and 32% of controls, respectively, by 24 hours. Second, light assimilation curve analysis demonstrated that 24 hour exposure to feeding causes a significant 25% decline in the light-saturated maximum rate of photosynthesis, without affecting the rate of respiration. Third, assimiliation-internal carbon dioxide analysis demonstrated that 24 hour exposure leads to variable but no significant effect on the maximum rate of carboxylation by Rubisco, the PAR-saturated rate of electron transport, and the rate of triose phosphate utilization. This final result is counter to the suggestion that this species causes end-product inhibition of photosynthesis, and instead suggests that stomatal behavior is the cause for reductions in gas exchange processes in injured plants. Our results differ from those with other hopperburning hemipterans, suggesting differences in mechanisms of injury among hopperburning species.

Volatile organic compounds of teak and behavioral responses of termites to teak volatiles

Prodpran Thakeow[1], Sergio Angeli[2]

[1]Chiang Mai University, Thailand, [2]Free University of Bolzano, Italy

Termites are the most destructive insect pests of wood. However, in Thailand teak (Tectona grandis) has been a popular constructing material for centuries because it is a well-known termite-resistant timber. In this research, we aimed to investigate the behavior of termites towards teak extract. Teak sawdust was extracted using dichloromethane and methanol as solvent. Then volatile organic compounds (VOCs) released directly from sawdust and from the extract were analysed using SPME-GC-MS. In addition, the chemical compositions of the extract were analyzed by LC-MS. VOCs released by teak sawdust belong to several chemical groups, i.e. alcohols, aldehydes, ketones, hydrocarbons, esters, and terpenes. There were 12 VOCs detected in headspace of teak sawdust and 33 VOCs identified in the extract. These compounds were, for example, 3-methyl-2-butenal, octane, nonane, α-pinene, β-pinene, 6-methyl-5-hepten-2-one, decane, hexyl acetate, limonene, undecane, and nonanal. Interestingly, some VOCs detected in sawdust headspace were not found in the extract. 2-Hydroxymethyl anthraquinone was found in the extract. This compound is a biologically active substance. The behavioral responses of termites to the characterized teak VOCs will be further described and discussed.

Coordinated monitoring, forecasting and risk warning systems for field crop insects in western Canada

Jennifer Otani[1], Scott Meers[2], Scott Hartley[3], John Gavloski[4], Lloyd Dosdall[5], Hector Carcamo[6], Owen Olfert[7]

[1]AAFC, Canada, [2]Government of Alberta, Canada, [3]Government of Saskatchewan, Canada, [4]Manitoba Agriculture, Canada, [5]University of Alberta, Canada, [6]AAFC, Canada, [7]AAFC, Canada

The production area for field crops in Canada is extensive; the Prairie Ecoregion alone contains approximately 30 million hectares of cropland. Insect pest outbreaks are periodic/cyclical in nature. Production risks from insect pest outbreaks can be minimized through a coordinated monitoring program that provides decision-support to the agriculture industry in a timely manner. Also, monitoring of beneficial organisms is critical to their conservation and to the development of reduced-risk strategies for management of pest species. Climate change, new agronomic practices and new crops affect pest populations and diversity of beneficial arthropods. Knowledge and information on pest status, occurrence, forecasting tools, risk assessment analyses, and other outputs are made available through a number of vehicles including databases, models, software, technology transfer reports and publications. Wind trajectory analysis for air parcels that may carry insect pests and plant pathogens are also utilized to assess the potential for pest movement over hundreds of kilometers. Using the data collected, timely risk warnings, provided as regional risk maps and accompanied with interpretive text, are produced in a format useful to the industry (electronically, field days, producer meetings).

Diamides (IRAC MoA Group 28) are a new class of insecticidal chemistry with a novel mode of action (ryanodine receptor modulator) that disrupt calcium movement in muscle cells resulting in rapid paralysis and feeding cessation. Flubendiamide which is a phthalic diamide was commercialized in approximately 2007 followed by registrations of chlorantraniliprole, an anthranilic diamide, a few years later. The diamides are highly effective against Lepidopteran pests and control insects resistant to other modes of action, thus creating the potential for over-dependency by growers. To maintain susceptibility of high risk insect pests to diamide products the IRAC International Diamide Working Group was created in 2008. They developed global IRM strategies for adaptation and implementation at the local level by country diamide IRM teams. The country IRM teams currently are comprised of IRAC company representatives and local influencers from academia, private industry, and extension. As of 2011, approximately 20 country IRM teams were created focusing on a few key insect pests. Additionally, the country teams are developing MoA communications and educational plans for influencers (trainers) and growers who will implement the IRM rotational strategies. The progress and accomplishments of these teams vary as some have been established for over two years while others are just being formed. Urgency to implement IRM strategies is necessary since Plutella xylostella resistance to diamide insecticides has already occurred in Thailand, Philippines, and Taiwan.

DuPont™ Cyazypyr™ (DPX-HGW86, cyantraniliprole), is the second anthranilic diamide insecticide (IRAC Group 28), to be commercialized but the first to demonstrate control of a cross-spectrum of different species and life stages of important insect pests in agriculture, seed treatment, and home and urban pest control sectors. The insect groups controlled include chewing pests (such as Lepidoptera, Dipteran leafminers and flies, beetles, weevils and sawflies), sucking pests (psyllids, whiteflies, leafhoppers, planthoppers and aphids), and rasping pests such as thrips. The mode of action is as a ryanodine receptor agonist causing rapid disruption of pest muscle function and resulting in rapid feeding cessation and other muscle-controlled insect activities. Due to the rapid feeding cessation of pest feeding plants are protected from direct damage during feeding and indirectly via reductions in pest-transmitted plant pathogens. Cyazypyr™ is efficacious through translaminar, foliar surface and soil application methods. It acts mainly through direct ingestion during pest feeding, so it has minimal impact on pest natural enemies. This allows products based on Cyazypyr™ to have outstanding selectivity to beneficials arthropods while still offering excellent pest control features. It also has low toxicity to mammals and other non-target vertebrates and invertebrates, excellent environmental fate profile, and also lacks cross-resistance with other classes of insecticides. These characteristics combine to make DuPont™ Cyazypyr™ an ideal complement to the integrated pest management (IPM) and insecticide resistance management (IRM) programs in integrated crop production systems.

Different spectrum of insecticide resistance in the peach aphid *Myzus persicae* (Sulzer) (Hemiptera: Aphididae) in populations from Beijing area, China

Ya-Jun Gong[1], Shu-Jun Wei[2], Bao-cai Shi[3], Jian-hua Liu[4], Xiao-jun Guo[5], Ying-nan Wang[6]

[1]Beijing Academy of Agriculture and Forestry Sciences, China, [2]Beijing Academy of Agriculture and Forestry Sciences, China, [3]Beijing Academy of Agriculture and Forestry Sciences, China, [4]Beijing Academy of Agriculture and Forestry Sciences, China, [5]Beijing Academy of Agriculture and Forestry Sciences, China, [6]Beijing Academy of Agriculture and Forestry Sciences, China

The peach aphid Myzus persicae (Sulzer) is one of the most serious pest worldwide. High pesticide resistance level to lead to the difficulty on the control of this pest. Here, the pesticide resistance level to five frequently used pesticides were tested by bioassay on six field populations and a sensitive population, and the kdr resistance was detected using bi-PASA PCR method. Esterase and acetylcholinesterase activity was tested using traditional methods. The results show that both the six field populations, i.e. Tongzhou, Shunyi, Daxing, Haidian, Yanqing and Mentougou and the sensitive population developed resistance to beta-cypermethr. The proportion of resistant homozygote is higher than 90% in all studied populations except for Yanqing and Daxing; Mentougou, Tongzhou and Yanqing populations developed resistance to chlorpyrifos and imidacloprid with resistance ratio of 2.05-4.24 and 32.03-41.27, respectively; All of the field populations are sensitive to abamectin and emamectin benzoate (resistance ratio is 0.19-1.44), except for the Daxing population (resistance ratio is 3.45 and 2.82, respectively) and Haidian population to abamectin (resistance ratio is 2.66); There is significant positive correlation between the esterase activity and resistance ratio to chlorpyrifos and imidacloprid, while there is negative correlation between acetylcholinesterase activity and resistance ratio of chlorpyrifos and imidacloprid.

Diversity and genetic differentiation of the whitefly *Bemisia tabaci* species complex in China based on mtDNA CO1 analysis

Xiaojun Guo[1], Chen Luo[2], Fan Zhang[3], Xiwu Gao[4]

[1]Beijing Academy of Agriculture & Forestry Scinece, China, [2]Beijing Academy of Agriculture & Forestry Scinece, China, [3]Beijing Academy of Agriculture & Forestry Scinece, China, [4]China Agricultural University, China

The whitefly Bemisia tabaci are considered as a taxonomically complex that contained some destructive pests. Two of the most prevalent cryptic species are B. tabaci Middle East-Asia Minor 1 (MEAM1) and Mediterranean (MED). In an extensive field survey of the B. tabaci complex present throughout part of China from 2004 to 2007, we obtained 93 samples of B. tabaci from 22 provinces. We determined that these Chinese haplotypes included 2 invasive species (MEAM1 and MED), and 4 indigenous cryptic species (Asia II 1, Asia II 3, China 3 and Asia II 7) by sequencing mitochondrial cytochrome oxidose 1 gene (mtDNA CO1).Prior to 2007, MEAM1 was a dominant species in many provinces in China. By 2007, MED was dominant in 11 provinces. Both invasive and indigenous species were simultaneously found in some regions. Indigenous species of B. tabaci were found in six provinces in southern China. MED and MEAM1 have broad ranges of host plants, and indigenous species appeared to have much narrower host ranges. All Asia II 3 samples were found on cotton except one on aubergine. China 3 has more host plants than Asia II 3. Twelve samples of China 3 were collected from sweet potato, Japanese hop, squash and cotton.MED showed a lowest degree of similarity than the other species. The data indicate that both MEAM1and MED were rapidly established in China.

Life cycle (developmental) stages of *Hymenia recurvalis* (f.) (Lepidoptera: Pyralidae) on susceptible amaranthus species in Ibadan south-west Nigeria

Ismaila Adeniran Aderolu[1], Amos Adebayo Omoloye[2]

[1]*University of Ibadan/ Cocoa Research Institute of Nigeria, Nigeria,* [2]*University of Ibadan, Nigeria*

Aderolu, I.A. and Omooloye, A.A. University of Ibadan, Ibadan, Nigeria *Correspondence: adeisma@yahoo.com; +234-8035862166 The life cycle stages of the Beetworm moth, Hymenia recurvalis (F.) [Lepidoptera: Pyralidae], was studied on Amaranthus cruentus (susceptible host plant) and the adult fed with 5% honey solution (in cotton swab) under ambient conditions of 27±3oC and RH 75% in the screen house to identify resistance donor. Data were collected on morphometrics of immature stages (mm), developmental period (days) and number of instars and sex ratio. Oviposition commenced three days after mating The development of H. recurvalis on A. cruentus spanned 32.7days comprising egg which measured 0.57±0.254 mm long, 0.40±0.0435 mm wide and 0.24±0.0418mm in height. Eclosion (4.2±0.084days); 1st Instar (3.2±0.051days); 2nd Instar (2.3±0.041days); 3rd Instar (3.2±0.044days); 4th Instar (3.1±0.044days); 5th Instar (5.2±0.032days); 6th Instar (5.1±0.037days); Pre-pupa (2.01±0.043days) and Pupa (9.7±0.082days). The sex ratio was 1:1.09 in favour of female. Adult longevity: female (Unmated=15.3±0.56; mated=22.2±0.80) and male (Unmated=11.5±0.43; mated= 14.1±0.53) varied significantly. Average adult wingspans were 19.95±0.0.196 mm and 18.18±0.115 mm for female and male respectively.

Investigation of occurrence and spatial distribution of *Pseudaulacaspis pentagona*(Targioni-Tozzetti) on peach trees in greenhouse

Yingnan Wang[1], Fan Zhang[2], Xiaojun Guo[3]

[1]Beijing Academy of Agriculture & Forestry Scinece, China, [2]Beijing Academy of Agriculture & Forestry Scinece, China, [3]Beijing Academy of Agriculture & Forestry Scinece, China

Pseudaulacaspis pentagona(Targioni-Tozzetti) is a kind of wide host range,feeding miscellaneous and reproductive ability pest,and has become a dangerous pest of fruit trees,garden flowers and economic forest in China for these years.With the development of peach trees in greenhouse in Beijing ,the occurrence and damage of P.pentagonaon had been reported. The occurrence,population distribution and spatial distribution pattern of P.pentagonaon on peach trees in greenhouse was investigated,which is basic work for effective prevention and control the pest.The results show that there are different damage among the peach species by P.pentagonaon. Which the number of female adults on flat peach orchard are significantly more than nectarine orchard,but there is no difference in number of male adults in both orchard. The population of the pests has a trend of aggregation in spatial distribution on peach trees in greenhouse,but no significant difference of damage is found between branches and bole.

Rapid expansion in geographic range of infestation of shiitake mushrooms by fungus gnat pest, *Neoempheria ferruginea* (Brunnetti) (Diptera: Mycetophilidae), in Japan

Masahiro Sueyoshi[1], Hiroshi Kitajima[2], Etsuko Kagaya[3]

[1]Forestry and Forest Products Research Institute, Japan, [2]Forestry and Forest Products Research Institute, Japan, [3]Forestry and Forest Products Research Institute, Japan

The Shiitake mushrooms, one of the edible fungi in Japan, have mainly been cultivated with sawdust-based artificial media in an indoor facility over the last two decades. The amount of the mushrooms cultivated with this method represented more than 80% of the overall total in Japan. The infestation of larvae of a fungus gnat, Neoempheria ferruginea, which was first reported in 1992, has now increased to cover 19 of the 47 prefectures in Japan. The mechanism of this rapid expansion in geographic scope remains indeterminate. The larvae of the fly inhabit the surface of the media and the fruit bodies of the mushrooms, thus contaminating the larvae into the commodity causes damage of the mushroom production. This pest must be effectively controlled to prevent further expansion in the current distribution. To test our hypothesis: human activities such as transportation of the contaminated media to be linked to the rapid expansion; we examined to trace the geographical expansion with the phylogenetic analysis. We also conducted an experiment of the oviposition to the medium. We suggest that some populations expanded their distributions anthropologically because some remote localities shared the same haplotype of the mitochondrial DNA and the females laid eggs even on the surface of the plastic bags containing the artificial media. We also collected probably two different species of Neoempheria from the infested media based on both morphological and phylogenetic analyses. We suggest that suitable treatment of the media contaminated with the eggs is one of the effective in controlling measures.

Specificity of pheromones traps for monitoring mealybugs in vineyards and pictoric key for males

Tania Zaviezo[1], Margarita Correa[2], Alda Romero[3], Paula Rojas[4]

[1]Universidad Catolica de Chile, Chile, [2]Universidad Catolica de Chile, Chile, [3]Universidad Catolica de Chile, Chile, [4]Universidad Catolica de Chile, Chile

Mealybugs (Hemiptera: Pseudococcidae) are key pest in vineyards worldwide. Their cryptic habit make them hard to monitor, but recently sex pheromone of several mealybug species have been identified and synthesized, including the most common species in Chilean vineyards. This has allowed the use of pheromone baited traps for their monitoring. Fields trials were carried out setting out traps for five mealybug species (two reported for Chile and three not known to occur) for two seasons in nine vineyards. Male mealybugs caught in traps were counted and a proportion identified to species using morphological keys. The proportion of males caught in the corresponding trap was determined and male counts on traps were contrasted with species detected by visual counts on plants. The most common species found visually was P. viburni, with very few P. longispinus observed, which corresponded with the level of captures in traps. Pseudococcus viburni traps had on average ten times more males than P. longispinus traps (226 versus 20 males per trap per season), and only 1.2 males per trap per season were captured in the traps of the other species. On average for the two seasons 93.5% of identified males in P. viburni traps corresponded to this species, and 98% in P. longispinus traps. None of the males caught in the traps of species not known from Chile were from those species, representing only accidental catches. A pictorial key of male genitalia was developed. In conclusion pheromone traps showed a high level of specificity in the field.

Seed treatment insecticide alternatives to manage soil insect pests of sugarbeet

Mark A. Boetel[1], Allen J. Schroeder[2], Robert J. Dregseth[3], Ayanava Majumdar[4]

[1]North Dakota State University, Fargo, ND, U.S.A., [2]North Dakota State University, Fargo, ND, U.S.A., [3]North Dakota State University, Fargo, ND, U.S.A., [4]Auburn University, Auburn, AL, U.S.A.

Soil-inhabiting insect pests frequently damage and cause severe economic loss in sugarbeet. Although conventional at-plant granular and liquid insecticide formulations have been used to manage these pests for decades, recently labeled insecticidal seed treatments have been widely adopted by producers in recent years. This research involved multiple field trials between 2004 and 2009 to compare insecticidal seed treatments with conventional insecticides for efficacy against natural infestations of the following: 1) sugarbeet root maggot, Tetanops myopaeformis Roder; 2) wireworms (Limonius spp.); and 3) subterranean Collembola (Onychiurus spp.). Excellent wireworm control was provided by the combination seed treatment Poncho Beta (clothianidin+betacyfluthrin applied at 60+8 g a.i./unit [100,000 seeds]), Cruiser 5FS (thiamethoxam; 60 g a.i./unit) seed treatment, and a conventional granular soil insecticide, Counter 15G (terbufos; 1.7 kg a.i./ha). Collembola control trials demonstrated that insecticidal seed treatments (i.e., Nipsit Inside [clothianidin; 60 g a.i./unit], Cruiser, and Poncho Beta) performed at similar levels to those of low and moderate rates (1 to 1.7 kg a.i./ha) of terbufos 15G. Seed treatment insecticides appear to be less likely than conventional insecticides to cause seedling phytotoxicity and associated yield losses in sugarbeet. The seed treatments we evaluated are likely to provide similar efficacy as moderate rates of currently labeled conventional soil insecticides for controlling wireworms and subterranean Collembola. A significant environmental benefit of seed treatment technology is that major (up to 95%) reductions in the amount of insecticide active ingredient are needed for adequate pest control in sugarbeet production.

Comparative evaluation of VOCs emitted by *Achillea collina* infested by aphids and mechanically damaged

Annamaria Giorgi[1], Sara Panseri[2], CN Nanayakkarawasam Masachchige[3], Manuela Mattara[4], Luca Chiesa[5], Giuseppe Lozzia[6]

[1]University of Milan, Italy, [2]University of Milan, Italy, [3]University of Milan, Italy, [4]University of Milan, Italy, [5]University of Milan, Italy, [6]University of Milan, Italy

Plants along the centuries evolved wide range of mechanisms to cope with biotic and abiotic stresses, including the emission of induced volatile organic compounds (VOCs), whose production is trigged by mechanical damage or pathogen infestation of plant tissues, providing them defensive tools (Arimura et al., 2005). This study focuses on VOCs emitted by Achillea collina Becker ex Rchb. as results of aphid infestation and mechanical damages. In particular it takes account of differences between compounds induced by the generalist Myzus persicae (Sulzer), the specialist Macrosiphoniella millefolii DeGeer aphid species infestation and two different types of mechanical injury (pin shoot and extended pressure). Headspace-Solid-Phase-Microexctraction and Gas-Chromatography/Mass-Spectrometry (HS-SPME-GC/MS) "in vivo" method was used to evaluate A. collina VOCs. We observe, in both aphids infestation a decrease of trans-2-hexenal associate with an increase of 2-hexen-1-ol and 1-hexanol, suggesting the activation of the methabolic pathway that leads to production of green leaf volatile compounds (Gatehouse, 2002). The same result was recorded in mechanically induced damages suggesting that in A. collina the production of these compounds is a non specific response to induced both by mechanically and aphids provoked injuries. Furthermore a decrease of some terpenes (β and γ-pinene) and the increase of others (α-phellandrene and isocaryophyllene) were recorded. The involvement of significantly varying compounds in tritrophic interaction mechanisms is also discussed.

Keywords:*Achillea collina, volatile organic compounds (VOCs), Myzus persicae (Sulzer), Macrosiphoniella millefolii DeGeer, HS-SPME-GC, MS*

Corn leaf aphid abundance in Cry3Bb1- and conventional-maize hybrids in South Dakota.

Billy Fuller[1], Rosemary Gutierrez[2], Bradley McManus[3]

[1]South Dakota State University, U.S.A., [2]South Dakota State University, U.S.A., [3]South Dakota State University, U.S.A.

A study to measure corn leaf aphid, Rhopalosiphum maidis (Fitch) abundance in corn rootworm, Diabrotica spp., resistant hybrids (Genuity® VT Triple PRO® corn) compared to conventional near isoline maize, Zea mays L., hybrids was conducted in eastern South Dakota during 2009 and 2010. The insect-resistant hybrid possessed a dual mode-of-action for above-ground insect protection in corn that is stacked with below-ground insect protection in addition its Roundup Ready® 2 herbicide technology. The Cry3Bb1 transgenic event was responsible for the resistance of this hybrid to corn rootworms. Plots were arranged in 9.2 meter square treatment areas (12 rows spaced 0.8 m apart) with 10 row buffers separations. To induce potential outbreaks of R. maidis, carbaryl insecticide was applied at 1.12 Kg[AI]/ha in half the plots on 10 July to eliminate beneficial arthropods and thus trigger later-season aphid resurgence. Aphid counts from whole-plant sampling were conducted by using a 2wk cycle from 10 August through 29 September. Aphid populations responded to the removal of predators and there were significantly more R. maidis found during sampling periods in treated conventional hybrid and Cry3Bb1 treatments. Additionally, we found greater aphid abundance in Cry3Bb1 plots over the near isoline irrespective of carbaryl treatments. The insect resistance hybrid was possibly more attractive to aphid colonization because they were unstressed from insect damage and withstood drought stress better than the near isoline.

[1]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India, [2]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India, [3]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu., India, [4]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India, [5]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India

The present study evaluated the role of entomopathogenic fungus, Isaria fumosorosea isolated from Alagar hill of Madurai dt, Tamil Nadu, India against Spodoptera litura in the laboratory as well as pests of cotton in the field. The results of the laboratory bioassay unveiled the susceptibility of S. litura to maximum of 80% reduction over control. The present study have recorded 3 (112±0.92 to 35±0.074) fold reduction of Aphids and 10 (11.13±0.86 to 1.6±0.002) fold reduction of Jassids in the field by I. fumosorosea. The probable reduction of bolls of cotton after spray has reduced drastically. It supports the suitability of virulent Ifr for the field cotton pest management.

Keywords:*Bioassay, Spodoptera litura, Isaria fumosorosea, Aphids, Jassids*

Development and Reproduction of *Ophraella communa* (Coleoptera: Chrysomelidae) on *Ambrosia artemisiifolia* and *Parthenium hysterophorus* and its Potential for Biological Control

Chin-Ling Wang[1], Chen-Shen Lai[2], Feng-Chyi Lin[3], Mou-Yen Chiang[4]

[1]Taiwan Agricultural Research Institute, Taiwan, [2]Taiwan Agricultural Chemicals and Toxic Substances Research Institute, Taiwan, [3]Taiwan Agricultural Research Institute, Taiwan, [4]Taiwan Agricultural Chemicals and Toxic Substances Research Institute, Taiwan

Ragweed (Ambrosia artemisiifolia L.) and parthenium weed (Parthenium hysterophorus L.) seriously affect agriculture, human and animal health, as well as the environment. Both these plants are invasive weeds in Taiwan. Chrysomelids, scales, mealybugs, tussock moths, and leafminers have been found on both these weeds. Among these phytophagous insects, the ragweed beetle (Ophraella communa LeSage) is the most promising species for biological control. The temperature range for their development was 20 ~ 32℃, their egg incubation period ranged from 4 to 10 days, larval developmental time was from 9 to 15 days, and pupation period was 5 to 9 days. Under the same temperature, immature developmental times were similar when fed on ragweed or parthenium weed. The emergence rates and number of eggs laid per female were higher on ragweed than on parthenium weed. At 28℃, females on ragweed laid more than one thousand eggs, which is about twice the number of eggs laid on parthenium weed. Compared with parthenium weed, that ragweed was a better host for this beetle to survive and reproduce. Ragweed or parthenium control with this chrysomelid in restricted spaces was successful. When beetles were released on either of these weeds, the plants were seriously damaged within several weeks. But in area without other host plants, adults placed on ragweed plants disappeared shortly after release. Establishment of field population is the next major problem to be solved for further use of this natural enemy for biocontrol.

Outcomes of intraguild interactions between two egg parasitoids in field and semi-field conditions

Valentina Amodeo[1], Antonino Cusumano[2], Ezio Peri[3], Paolo Lo Bue[4], Stefano Colazza[5]

[1]University of Palermo, Italy, [2]University of Palermo, Italy, [3]University of Palermo, Italy, [4]University of Palermo, Italy, [5]University of Palermo, Italy

Intraguild interactions between two egg parasitoids, Trissolcus basalis (Wollaston) and Ooencyrtus telenomicida (Vassiliev) exploring egg masses of the Southern Green Stink Bug Nezara viridula (L.) were investigated in field and semi-field conditions. Field trials were conducted in tomato fields by using sentinel and naturally laid egg masses in 2010 and 2011. Egg parasitoids monitoring, by sentinel egg masses placed weekly on plants during the tomato growing season and recollected one week later, showed that T. basalis occurs from June to October, whereas O. telenomicida occurs mainly in July and August. In the same fields, collections of naturally laid egg masses display different types of parasitized egg masses: only by T. basalis, only by O. telenomicida and by both species. The outcomes showed that T. basalis achieves a higher impact on the host population than O. telenomicida, even when multiparasitism occurs. Semi-field trials were conducted from July to September 2011, using pepper plants covered with mesh net in order to create small cages with five plants inside. In each cage, egg masses were placed on four plants located near to the cage corners and then T. basalis and O. telenomicida were released individually or simultaneously on the central plants. Egg masses were recollected after one week. The results showed that T. basalis achieves a high parasitization level when released alone but suffers competition by O. telenomicida when both species were simultaneously released.

Keywords:*biological control, competition, Nezara viridula, Trissolcus basalis, Ooencyrtus telenomicida*

Transmissibility of saffron infecting potyvirus in Iran by different aphid species

Shirin Parizad[1], Mina Koohi Habibi[2], Gholamhossein Mossahebi[3], Akbar Dizadji[4], Yasaman Moghaddasi[5]

[1]University of Tehran, Iran, [2]University of Tehran, Iran, [3]university of Tehran, Iran, [4]University of Tehran, Iran, [5]University of Tehran, Iran

Saffron (Crocus sativus L., Iridaceae) is the most expensive spice of the world and Iran, with 50000 ha saffron cultivation area, is the world's largest producer (> 90% of global production) of saffron. Infection of saffron plants with a potyvirus has been recently reported from Iran. Based on non-persistent transmission of potyviruses by aphid, this study was carried out to investigate transmissibility of this potyvirus by Aphis gossypii, A. fabae, Mayzus persicae and Acyrtosyphon pisum. Virus-free aphids were fasted for 2-4 h and then placed on infected saffron plants for an acquisition access period of 3-4 min. Afterwards, they were transferred in groups of five to the healthy saffron plants and Nicotiana benthamiana as positive control. Aphids were killed with an aphicide 24 h later and the plants transferred into an insect-proof glasshouse for 8 weeks. Detection of virus on inoculated plants was established by ACP-ELISA using potyvirus genus specific antibodies and reverse transcription PCR (RT-PCR) using potyvirus specific universal primer pairs at 14, 30 and 50 days after inoculation. The results showed that saffron infecting potyvirus was transmitted by A. faba into both saffron and N. benthamiana. The virus was not detected in saffron plants which were inoculated by other aphids, while it was detected in inoculated N. benthamiana plants. Therefore infected corms and A. faba are important factors of virus distribution in saffron fields.

Keywords:*Saffron, potyvirus, ACP-ELISA, RT-PCR, Aphis gossypii, Aphis fabae, Mayzus persicae, Acyrtosyphon pi*

Development and implementation of an area-wide management of Asian citrus psyllid (*Diaphorinacitri*Kuwayama) in Texas

Mamoudou Setamou[1], David Bartells[2], Matt Ciompelik[3], John V. da Graca[4]

[1]Texas A&M University-Kingsville, U.S.A., [2]USDA APHIS-PPQ-CPHST, U.S.A., [3]USDA APHIS-PPQ-CPHST, U.S.A., [4]USDA APHIS-PPQ-CPHST, U.S.A.

The Asian citrus psyllid, DiaphorinacitriKuwayama, is one of the known vectors of the currently incurable and deadly citrus greening disease or Huanglongbing (HLB). The insect is an introduced invasive species in the United States, and together with its vectored greening disease, D.citri is threatening the profitability and sustainability of the U.S. citrus industry. Due to its high mobility and high reproductive potential, this disease vector is very difficult to manage using local grower-level control approaches. This study presents strategies for the development and implementation of a pro-active area-wide management program for D. citri in Texas. The goals were to evaluate the importance of a dormant spray that targets overwintering adult psyllid populations and to demonstrate the viability of a regional control program over a local spray strategy. In a year-long-field study throughout 2008, a dormant spray application over a regional level provided effective control of D. citrifor 4 months, twice as long as with the local dormant spray approach. Throughout the year, the regional control program significantly reduced D. citripopulations over a large area thus preventing rapid re-infestation of groves by the pest, while only short term population suppressions were obtained with the local spray program. Grower participatory trials conducted in 2009 and 2010 showed that although coordination of the area-wide spray program is feasible during the dormant season its implementation during the active growing season from March to September is very difficult in Texas.

Selection and characterization of a *Spodoptera frugiperda* strain resistant to transgenic maize expressing a *Bacillus thuringiensis* protein

Natalia Alves Leite[1], Simone Martins Mendes[2], Thais Patricia Moreira Teixeira[3], Eliseu Jose Guedes Pereira[4]

[1]Univervidade Federal de Vicosa, Brazil, [2]Embrapa Milho e Sorgo, Brazil, [3]Univervidade Federal de Vicosa, Brazil, [4]Univervidade Federal de Vicosa, Brazil

Availability of laboratory-selected insect strains is important to assess the potential for resistance development in the field and to improve resistance management strategies to transgenic plants. Transgenic maize event TC1507, expressing the Cry1F protein from Bacillus thuringiensis, has been used effectively for management of Spodoptera frugiperda (Lepidoptera: Noctuidae) in Brazil. A strain of S. frugiperda, obtained from field collections in Minas Gerais state in 2010, was selected in the laboratory for resistance to Cry1F using leaves of TC1507 maize plants in two selection regimes. Chronic exposure of larvae to the event was more effective than gradual exposure in the selection of resistant S. frugiperda individuals. After only four generations of selection a strain with significant levels of resistance to Cry1F was obtained, as indicated by survival of insects recovered from Cry1F maize plants in the greenhouse. Importantly, selection for Cry1F resistance did not affect the survival of the selected strain in maize hybrids expressing Cry1Ab or the stack of Cry1Ab.105 and Cry2Ab2, indicating no cross-resistance between these toxins and Cry1F. Additionally, reciprocal crosses between control and the Cry1F-selected insects revealed that the resistance is autosomal and incompletely recessive, and there was no apparent fitness costs associated with the resistance. The results of this investigation have important practical implications for resistance management, which will be discussed in the poster. The availability of this resistant strain provides an opportunity to refine recommendations for resistance management strategies of S. frugiperda to transgenic maize expressing B. thuringiensis toxins.

Assessment of *Harmonia yedoensis* Takizawa (Coleoptera: Coccinellidae) as a new agent for biocontrol

Ekaterina N. Balueva[1], Taeho Kim[2], Jong Wook Lee[3]

[1]Yeungnam University, Russia, [2]Bio-resource Research Institute, Dongbu Farm Ceres, Republic of Korea, [3]Yeungnam University, Republic of Korea

In this study we try to reveal possibility for use of Harmonia yedoensis Takizawa in the biocontrol. H. yedoensis by several parameters of fitness, at comparison with Harmonia axyridis Pallas, was estimated. The total voracity of larvae H. yedoensis was greater than that of H. axyridis in all variations of the experiment. When using Myzus persicae and Sitobion avenae as prey, the voracity of H. yedoensis larvae was significantly greater than that of H. axyridis. Also, significant differences in developmental time of the immature stages were observed between tested species of ladybirds with S. avenae as prey; the time of development of larvae H. axyridis was shorter (10.2±0.18 days) than that for H. yedoensis (8.2±0.14 days). The survival rate of the immature stages was high for both species of ladybirds. But when using M. persicae as prey, the survival rate of pupae decreased by 30 % for H. yedoensis and by 15 % for H. axyridis compared with S. avenae. The first results of an assessment of H. yedoensis testify to the potential high fitness of this species for biocontrol. After some selection, H. yedoensis could be introduced in existing technologies of mass rearing of aphidophagus-ladybirds and could replace H. axyridis in the modern systems of plant protection.

Monitoring Pesticide Resistance of Two Spotted Mite, *Tetranychus urticae* in Rose Greenhouses in Korea

Bu-Keun Chung[1], Byoung-Ryoung Jeong[2], Si-Hyeok Lee[3], Tae-Soo Chon[4], Siwoo Lee[5]

[1]Gyeongsangnam-do, Agricultural Research & Extension Services, Republic of Korea, [2]Gyeongsang National University , Republic of Korea, [3]Seoul National University, Republic of Korea, [4]Pusan National University, Republic of Korea, [5]National Academy of Agricultural Science, RDA, Republic of Korea

Abstract Tetranychus urticae was collected from greenhouse roses to monitor the development of acaricide resistance. Dose-mortality lines were estimated on 16 regional populations with 13 acaricides. For each acaricide, LC50s of the populations were plotted to check normality. LC50s of eight acaricides showed normal distribution and five others did not. An index of Ln(recommended dose/LC50 for each acaricide) checked the development of resistance to populations. The index is based upon recommended dose to control a pest stage and empirical LC50 got from serial dilution range for each pesticide. We tried to categorize acaricides by index due levels of effectiveness to mites: tebufenpyrad, fenpyroximate, bifenthrin, and fenbutatin oxide as non-effective acaricides with less than index 1.0, chlorpyrifor+bifenthrin and milbemectin as alert level placed between 1.0 and 2.0, acequincyl as caution between 2.0 and 3.0, and abamectin, cyflumetofen, bifenazate, chlorfenapyr+fulacrypyrim and propargite as effective over 3.0. We also tested the similarity of acaricide actions for choosing effective acaricides against resistant mites and of populations for resistance management. We could make several acaricides groups: group1 including abamectin, cyflumetofen, and bifenazate; group 2 propargite and chlorpyrifos+bifenthrin; group 3 chlorfenapyr and acequinocy; and group 4 mibemectin, fenyroximate, and bifenthrin, by which we can suggest not to use acaricide within the same group to avoid the resistance development. Populations grouping would imply similar practices of acaricide use, so we can manage pesticide usage, effectively. Group A includes Gimhae 2, 3, 4, 5, Jincheon2, and Taean, and Group B includes Goyang, Gangjin1, Paju, Gangin2 and Namwon.

Larvicidal and repellent activity of Korean endemic *Thymus magnus* Nakai against the Asian tiger mosquito, *Aedes albopictus*

Young-Uk Park[1], hyun-na Koo[2], Gil-Hah Kim[3]

[1]Department of Plant Medicine, Chungbuk National University, Republic of Korea, [2]Chungbuk National University, Republic of Korea, [3]Chungbuk National University, Republic of Korea

The repellent and larvicidal activity of dagalet thyme, Thymus magnus Nakai was assessed against the Asian tiger mosquito, Aedes albopictus. Intact whole plants of T. magnus proved to have a repellent activity of 91.2% against female Ae. albopictus. The volatile compounds of T. magnus were determined by gas chromatography-mass spectrometry as follows: ?-terpinene (33.0%), thymol (29.9%), ?-bisabolene (8.9%), ?-cymene (8.3%), ?-terpinene (5.0%), myrcene (4.7%), ?-caryophyllene (4.0%), ?-thujene (2.7%), camphene (1.3%), carvacrol (1.2%), and ?-pinene (1.1%). Among these candidates, thymol exhibited complete (100%) repellent activity against the female Ae. albopictus, an effect that was confirmed through evaluating the electrophysiological response on the antenna of Ae. albopictus. Duration of effectiveness was produced by a binary 1:2 mixture of thymol and vanillin (0.05:0.1 ?L cm-2) that was found to be significantly more effective than thymol alone for a period of 90 min. In addition, thymol, ?-terpinene, and carvacrol showed high larvicidal activity on the third instar larvae.

Within-tree Distribution of *Dialeurodes citri* (Homoptera: Aleyrodidae) Immature on Citrus Trees

Jeong Heub Song[1], Soon Yeong Hong[2], Shin Chan Lee[3], Seong Geun Kang[4]

[1]Jeju Agricultural Research & Extension Services, Republic of Korea, [2]Jeju Agricultural Research & Extension Services, Republic of Korea, [3]Jeju Agricultural Research & Extension Services, Republic of Korea, [4]Jeju Agricultural Research & Extension Services, Republic of Korea

Citrus whitefly, Dialeurodes citri (Ashamed), is a minor pest of citrus in Jeju, South Korea. The occurrence of this pest is gradually increasing, especially in organic farming citrus orchards. Within-tree distribution of nymphs of D. citri on leaves of citrus, Citrus unshiu Marcow., trees were studied in orchard plots for application of entomopathogenic fungi, Aschersonia aleyrodis as biological control agent. Distribution of nymph stage depended on leaf position in a twig. The leaves with most abundance and low variation of citrus whiteflies were leaf 4th from a twig base. Taylor's power law provided better description of mean-variance relationship for the indices than Iwao's patchiness regression. The minimum sample size was estimated from the parameters of Taylor's power law for leaf 4th at precision levels of 0.20, 0.25 and 0.30. The sample size increased with improving precision level and decreased with increasing density of nymphs. The analysis of variance of two-stage sampling was used to estimate the number of sampled leaves per tree. The estimated variance decreased with increasing the number of sampled tree and sampled leaves a tree. The six leaves per tree was estimated as the optimum sampled leaves.

Occurrence Tendency of Major Pests in Korean Apple Orchards for Past 20 Years

KyungHee Choi
National Horticultural & Herbal Science, RDA, Republic of Korea

The annual occurrence of major pests and the damages by its were surveyed and analyzed at sixteen to thirty apple orchards belongs to four to eight major apple producing districts from 1999 to 2011. In mites, Tetranychus urticae showed the highest in orchard rates of occurrence as well as heavy population until 1990's, but the damaged orchards(%) was changed to Panonychus ulmi, even though the population density of Tetranychus urticae was still highly occurred. In aphids, Myzus malisuctus showed the difference by year, 0~38 % in orchard rates of occurrence and 0~2.5% in damaged leaf rates. But Aphis citricola showed higher in orchard rates of occurrence and showed big difference in population density according to year. In Lyonetiidae, Phyllonorycter ringoniella after 2000's has lowered pattern in the orchard rates of occurrence and damaged leaf rates compare to the beginning of 1990's. Lyonetia prunifoliella in the beginning of 1990's has showed pattern increased damaged leaf rates as sharply increased orchard rates of occurrence but decreased these rates after 2009. in the fruit moths, orchard rates of occurrence showed in 5~67% and damaged fruit rates in 0.01~3.1%, with difference by year. Since 1998, orchard rates of occurrence and damaged fruit rates of Grapholita molesta was showed higher continuously. In leafroller, orchard rates of occurrence and damaged fruit rates showed decreased patterns since on the beginning of 2000's. These population fluctuation on each major pests was compared to the annual weather (precipitation and mean temperature), areas of orchards and current status of agrochemical

Control effect of mating disruption, Confuser R and Isomate KR to fruit moths in Korea apple orchards

KyungHee Choi[1], SoonWon Lee[2]

[1]National Horticultural & Herbal Science, RDA, Republic of Korea, [2]National Horticultural & Herbal Science, RDA, Republic of Korea

The control effect of Confuser R and Isomate KR, newly developed mating disruption to two fruit moths, Grapholita molesta and Carposina sasakii was assessed at the two organic apple orchards in Chilgok and Chungsong provinces, which was composed of four treatments; treatment of mating disruption Confuser R, treatment of mating disruption Isomate KR, no treatment of mating disruption and no treatment of synthetic pesticides(NTMD+NTSP), no treatment of mating disruption and classical treatment of synthetic pesticides(NTMD+CTSP). Annual monitoring using sex-pheromone traps for Grapholita molesta and Carposina sasakii in NTMD+NTSP fields were counted higher numbers as 457, 323 in Chilgok, respectively and 318, 30 in Cheongsong, respectively. Damaged fruit ratio by Grapholita molesta and Carposina sasakii before the harvest was recorded 14.3, 34.3% in Chilgok and 28.8, 10% in Cheongsong, respectively. Confusor R and Isomate KR treated orchard was exhibited the mating Inhibition ratio of Grapholita molesta adults over 99.8% in all Chilgok and 99.1 and 92.8% in Cheongsong areas. For Carposina sasakii, mating inhibition ratio was perfect. When treated Confusor R and Isomate KR, damaged fruit ratio was showed the control effect over 95% with no statistical difference to NTMD+CTSP. From above results, newly developed chemicals (Isomate KR) have the similar control efficacy with commercially registered chemicals (Confusor R) to two fruit moths

Recent Occurrence Status of Three Major Species of Fruit Moths in Apple Orchards

Hyangmi Kim[1], Il Jang[2], SoonWon Lee[3], Yoon Jung Kim[4], Joo hee Song[5], Kyung Hee Choi[6], Nak Sam Seong[7]

[1]Korea Fruit Pest Forecasting Research Center, Republic of Korea, [2]Korea Fruit Pest Forecasting Research Center, Republic of Korea, [3]Korea Fruit Pest Forecasting Research Center, Republic of Korea, [4]Geochang Agriculture Technical Center, Republic of Korea, [5]Jangsu Agriculture Technical Center, Republic of Korea, [6]Apple Research Station, NHRI, RDA, Republic of Korea, [7]Geochang Agriculture Technical Center, Republic of Korea

The study was conducted to investigate the population fluctuation on three major internal feeders, Grapholita molesta, Grapholita dimorpha, and Carposina sasakii, of six apple production regions of Korea from 2010 to 2011. The adult emergence of G. molesta, G. dimorpha and C. sasakii was examined by using pheromone traps. The population density of three species was ranked as follows: G. molesta > G. dimorpha > C. sasakii. The occurrence ratio of G. molesta, G. dimorpha and C. sasakii was 61.6, 28.3 and 10.1% in 2010, and 44.2, 40.6, 15.2% in 2011. The difference of occurrence ratio among was significant among apple orchards and between experimental years. The average number of G. molesta, G. dimorpha and C. sasakii caught on pheromone traps was 508.6(109 ~ 1,190), 233.2(16 ~ 797), and 83.4(1 ~ 255) in 2010, and 398.6(171 ~ 701), 366.3(186 ~ 758), and 137.0(14 ~ 468) in 2011. G. molesta and G. dimorpha adult was emerged from mid of April to late September and they have three or four generations per year. The first peak of overwintering G. molesta adult was showed on late April or early May. The first peak of overwintering G. dimorpha adult was later than that of G. molesta. C. sasakii has one or two generation per year.

Recent Occurrence Status of *Panonychus ulmi* and *Tetranychus urticae* in Apple Orchards

Il Jang[1], SoonWon Lee[2], HyangMi Kim[3], Yoon Jung Kim[4], NakSam Seong[5]

[1]Korea Fruit Pest Forecasting Research Center, Republic of Korea, [2]Korea Fruit Pest Forecasting Research Center, Republic of Korea, [3]Korea Fruit Pest Forecasting Research Center, Republic of Korea, [4]Geochang Agriculture Technical Center, Republic of Korea, [5]Geochang Agriculture Technical Center, Republic of Korea

The study was conducted to investigate the population fluctuation of two major spider mites, Panonychus ulmi (ERM) and Tetranychus urticae (TSSM) on 107~160 apple orchards of five apple production regions (Boeun, Yesan, Gunwi, Eusung and Bonghwa) of Korea from 2009 to 2011. The population density of TSSM was also examined on broad leaf weeds underneath the main apple trunk. The average occurrence rate of ERM and TSSM for three years was 17.0 (10.7 ~ 29.6) and 10.7(0.9 ~ 20.6)%. The average occurrence density of ERM and TSSM for three years was 8.1(1.6 ~ 26.7) and 4.3(0.01 ~ 12.0). The occurrence rate and density of ERM per year were presented as follows: 2010 > 2009 > 2011 and 2009 > 2010 > 2011. The occurrence rate and density of TSSM were ranked as follows: 2009 > 2011 > 2010. The occurrence rate of two spider mites per year was different among apple orchards. The population density of two species was highest on mid of May. The occurrence density and rate of TSSM on weeds for three years were 1.2 mites and 5.2%. The density of TSSM on weeds was lower than that of TSSM on the leaves of trees. The occurrence trend of TSSM on weeds was opposite to that on leaves of trees.

Oviposition model of *Frankliniella occidentalis* (Pergande) (Thysanoptera: Thripidae)

Sun Kyung Lee[1], Marana Park[2], Ju Won Yoo[3], Joon-Ho Lee[4]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Department of Agricultural Biotechnology, Seoul National University, Republic of Korea, [4]Department of Agricultural Biotechnology, Seoul National University, Republic of Korea

Frankliniella occidentalis, a vector of tomato spotted wilt virus (TSWV), has spread nationwide with damage to vegetables and floricultural crops in South Korea. To develop oviposition model of this species, we investigated F. occidentalis adult females longevity and total fecundity from 13-20 individuals at constant temperatures (16, 19, 22, 25, 28, 31 and 35℃) and a photoperiod of 14:10 (L:D) h. The longevity was longest as 29.83±5.43 (mean ± SE) days at 16℃ and was shortest as 1.25±0.01 (mean ± SE) days at 35℃. Ovipositon did not occur at 35℃, and total number of eggs laid was fewest at 28℃. Temperature-dependent development was well described by Logan 6 model (r2=0.93), and were used to calculate the adult physiological age. The relationship between total fecundity and temperature was well described by the Taylor model (r2=0.80). Age-specific oviposition and survival rate were well explained by the three-parameter Weibull function (r2=0.87) and the sigmoid function (r2=0.89), respectively. F. occidentalis oviposition model was constructed by total fecundity model, age-specific oviposition rate model and age-specific survival rate model.

Keywords:*Frankliniella occidentalis, Ovipositon model, Temperature*

Enhanced repellency against *Aedes aegypti* by composition of plant essential oils with vanillin addition and its application

Seung-jae Baeck[1], Soon-il Kim[2], June-sun Yoon[3], Sung-hwa Lee[4], Young-joon Ahn[5], Hyung wook Kwon[6]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]LG Electronics Inc., Seoul, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Seoul National University, Republic of Korea

Six plant essential oils, vanillin, and their mixtures were tested for repellent activities against a dengue virus vector mosquito Aedes aegypti (L.). These essential oils showing strong biological activities in fumigant toxicity test also gave repellent activities. Compared with 5% N, N-diethyl-3-methylbenzamide (DEET) of the six essential oil concentrations did not show repellent effects. However, a mixture of lemongrass oil, xanthoxylum oil, and vanillin (1:3:1, vol:vol:wt) showed that mixtures of essential oils with vanillin showed 270 min of complete protection time (CPT) compared with 247.5 min CPT with 15% DEET. The CPT depended on concentration of vanillin or on both factors. When we applied a mixture of lemongrass oil: xanthoxylum oil: vanillin (1:1:1, vol:vol:wt) to the Viscopearl formulation, or porous cellulose beads that provide gradual release of volatile compounds. Experiment showed 90% of repellency for 2 h. The insecticide and repellent behavioral approaches we drew upon in our current study insist that mixtures of vanillin and plant essential oil showed strong and durable repellency to the mosquito. Our study also indicates that personal repellents using mixtures of plant essential oils with vanillin were possibility applicable to spatial repellents and viable commercial product.

Keywords:*Aedes aegypti, mosquito, plant essential oils, vanillin, repellency*

The effect of exposure to a pulsed yellow light-emitting diode (LED) on the adult flight behavior of the cotton ballworm, *Helicoverpa armigera*

Jungbeom Yoon[1], Masashi Nomura[2], Satoshi Ishikura[3]

[1]*Graduate School of Horticulture, Chiba University, Japan,* [2]*Graduate School of Horticulture, Chiba University, Japan,* [3]*Hiroshima Prefectural Technology Research Institute, Japan*

Yellow fluorescent light irradiation has been commonly used for pest control of noctuid moths in various cultivated fields in Japan, but this method cannot be used in chrysanthemum fields because chrysanthemums produce buds only under the short-day condition. Therefore, an experiment was carried out to clarify the pulse conditions of a yellow LED required to control noctuid moths without suppressing the blooming of chrysanthemum. We used a lemon-yellow LED (central wavelength: 571nm) of similar wavelength to yellow fluorescent light, with intensity of 20mW/m² and pulsed-LED light period of 20ms. We observed the flight activity of adults of Helicoverpa armigera (Hubner), under various ratios of light to dark period of the LED pulse, 20ms:0ms (continuous lighting), 20ms:40ms, 20ms:80ms, 20ms:160ms and 20ms:400ms, using the actograph system in a 12-hour dark phase and compared the result with the 0ms:0ms (no lighting in the dark phase) using the same system. The results suggested that the flight activity of unmated males and females was generally at a lower level with 20:40 and 20:80 and it became clear to control the flight activity for five days continuously. However, the activity levels increased gradually unmated females with 20:0, 20:160 and 20:400, males with 20:0 and 20:400 in the dark phase with progress of a day, suggesting that the cotton bollworm became accustomed to the LED lighting conditions over days. Thus we considered that the flight behaviors (including feeding and reproduction behavior) of the adult moth was strongly suppressed under the conditions of 20ms:40ms and 20ms:80ms pulsed-LED light.

Interactions between Tannic acid and *Bacillus thuringiensis* subsp. kurstaki KB100 against *Spodoptera exigua*

Na Young Jin[1], Chang soon Kwak[2], San Na Oh[3], You Kyoung Lee[4], Mi Jin Jeon[5], Mi Ja Seo[6], Young Nam Youn[7], Yong Man Yu[8]

[1]Chungnam National University, Republic of Korea, [2]Chungnam National University, Republic of Korea, [3]Chungnam National University, Republic of Korea, [4]Chungnam National University, Republic of Korea, [5]Chungnam National University, Republic of Korea, [6]Chungnam National University, Republic of Korea, [7]Chungnam National University, Republic of Korea, [8]Chungnam National University, Republic of Korea

Bacillus thuringiensis subsp. kurstaki KB100 isolated from the domestic soil have the most effective activity against larva of Spodoptera exigua. The tannic acid as protease inhibitor might be increased the efficacy of sublethal concentrations of B. thuringiensis. We identified tannic acid as protease inhibitor that increased the efficacy of sublethal concentrations of B. thuringiensis. Mixture of B. thuringiensis and tannic acid was investigated the mortality of S. exigua larva in the laboratory and field. When B. thuringiensis treated to 2nd larva of S. exigua, mortality was shown 54.4%. However, mixtures of B. thuringiensis with 4 and 40 mM tannic acid were increased mortalities to 2nd larva of S. exigua as 64.0 and 95.5%, respectively. In the welsh onion field, the accumulated mortalities of 3 times replicated with mixture of B. thuringiensis and 40 mM tannic acid were 83.9, 89.4 and 66.8% compare with 61.8, 80.4 and 47.3% as only B. thuringiensis treatment, respectively. Excessive degradation of activated toxin was observed in S. exigua midgut juice detected by SDS-PAGE. But tannic acid successfully prevented the excessive degradation of protoxin in S. exigua midgut juice by SDS-PAGE.

Seasonal Occurrence of *Riptortus pedestris* on Hairy Vetch and Its Development and Longevity on Host

Hye Ri Kwon[1], Min Woo Park[2], Shin Hyuk Jo[3], Sae Hee Kim[4], Mi Ja Seo[5], Yong Man Yu[6], Young Nam Youn[7]

[1]Chungnam national University, Republic of Korea, [2]Chungnam national University, Republic of Korea, [3]Chungnam national University, Republic of Korea, [4]Chungnam national University, Republic of Korea, [5]Chungnam National University, Republic of Korea, [6]Chungnam National University, Republic of Korea, [7]Chungnam National University, Republic of Korea

The seasonal occurrence of R. pedestris was investigated using pheromone traps baited with its aggregation pheromone in the fields with various crop compositions in 2010 and 2011. The incoming of R. pedestris into the experimental fields began to catch from late-April. After seed gathering season in mid-July, the incoming rate of R. pedestis decreased, and the activity was continually observed till early-December. Otherwise, during the two years of the investigation, thirty-eight species of hemiptera including R. pedestris collected, which indicated abundant species diversity in hairy vetch fields. However, in the laboratory, R. pedestris could not developed successfully to adult stage as a host plant with only seed and plant of hairy vetch, with decreasing survival rate after 4th instar and the failure of emergence to adult stage. Also R. pedestris showed higher preference on soybean than hairy vetch. Consequently, hairy vetch may be not a suitable host for the development and survival of R. pedestris. It is considered that R. pedestris that R. pedestris is a temporary visitor at the season of seed formation in hairy vetch fields.

Antifeedant activity and electrophysiological response of *Ailanthus altissima* against *Plutella xylostella* (Lepidoptera: Plutellidae)

Hyun Na Koo[1], Jin-Won Jeong[2], Gil-Hah Kim[3]

[1]Chungbuk National University, Republic of Korea, [2]Chungbuk National University, Republic of Korea, [3]Chungbuk National University, Republic of Korea

Antifeedant activity of crude extracts of Ailanthus altissima leaf was studied against third instar larvae of diamondback moth, Plutella xylostella L. (Lepidoptera: Plutellidae). During preliminary screening, the methanol extracts were tested at 5,000 ppm concentration. The methanol extract was further separated with hexane, chloroform, ethyl acetate, and water, in order. The chloroform solubles, which observed significant antifeedant activity, were subjected to open column chromatography on silica gel. And then five fractions (C1 ? C5) were obtained. Of these fractions, second fraction (C2) showed good antifeedant activity with 98.7%. The C22 and C23 fractions isolated via recycling open column chromatography on silica gel exhibited high antifeedant activity. These two fractions were separated using ODS open column chromatography. As a result, C231 fraction showed the highest antifeedant activity and also showed significant difference in medial styloconic sensilla of last larvae of P. xylostella at electrophysiological response using oscilloscope. The C231 fraction was re-isolated and purified by HPLC and recycling, finally obtained the bioactive compounds. The structure of bioactive compound isolated was confirmed by LC-mass, 1H-NMR (500 MHz), and 13C-NMR (100 MHz).

Comparison of Plasmid DNA and cry Gene in *Bacillus thuringiensis* subsp. aizawai KB098 and Their Mutants

Mi Jin Jeon[1], Na Young Jin[2], Chang Soon Kwak[3], San Na Oh[4], You Kyoung Lee[5], Mi Ja Seo[6], Young Nam Youn[7], Yong Man Yu[8]

[1]Chungnam National University, Republic of Korea, [2]Chungnam National University, Republic of Korea, [3]Chungnam National University, Republic of Korea, [4]Chungnam National University, Republic of Korea, [5]Chungnam National University, Republic of Korea, [6]Chungnam National University, Republic of Korea, [7]Chungnam National University, Republic of Korea, [8]Chungnam National University, Republic of Korea

Bacillus thuringiensis subsp. aizawai KB098 is a high insecticidal activity against Spodoptera exigua. Insecticidal effective crystal was manifested (revealed) by cry gene. Cry gene is generally existed on the plasmid DNA of Bacillus thuringiensis. To find a factor which controls the formation of crystal, mutants were made by incubating KB098 at 42℃ (MKB-130) or irradiating UV (KBM-1). According to bioassay results, mutants didn't have toxicity and make a crystal. By extracting the plasmid DNA of KB098 and mutants, plasmid DNA encoded cry gene were confirmed. KB098 isolates had 4 cry genes, cry1Aa, cry1Ab, cry1C, cry1D, and also had been found seven plasmid DNAs. Contrary to plasmid DNA pattern of KB098, MKB-130 incubated at 42℃, however, left out the biggest plasmid DNA expected to encode cry gene. In result of PCR, 4 cry genes were not confirmed. KBM-1 irradiated UV didn't delete the biggest plasmid DNA expected to encode cry gene. As a result of plasmid DNA of KBM-1, there were conformed 4 cry genes similar to KB098. KBM-1 does not make crystal and there is no any toxicity against Spodoptera exigua. It is supposed that the sequence of plasmid DNA may be changed in the amplified cry gene.

Bacillus thuringiensis is a gram-positive, aerobic and spore forming bacterium. B. thuringiensis is usually found and isolated from natural environments, for example, soil, warehouse, leaf surface, grasses and insect habitats, and world widely used as biotic pesticide. In this study, biological activities of B. thuringiensis CAB530 strain from Anomala albopilosa (Coleoptera) were examined. The number of colonies of B. thuringiensis CAB530 was 6.61 × 108 cfu/㎖. Bipyramidal crystal was produced from B. thuringiensis CAB530 by confirmed with phase contrast microscope. B. thuringiensis CAB530 observed the band at 130kDa carried out SDS-PAGE that is similar to B. thuringiensis subsp. Kurstaki that is an insecticidal activity against Spodoptera exigua. Five genes, for example, cry1Aa, cry1Ab, cry1C, cry1D, cry1F, cry1I were observed with PCR. LC50 values of B. thuringiensis CAB530 against S. exigua and Plutella xylostella showed a high toxical activity as 1.6 × 105 and 7.75 × 104 cfu/㎖, respectively.

Most of organic farming use the green manure crop for replace chemical fertilizer. We surveyed the species of disease and insect pest on green manure crop, pear and persimmon, and biological diversity as different surface management methods(hairy vetch planting, grass planting, clean-tilled crops) in orchard. The species of disease and pest on hairyvetch and grass was Bacterial spot, sclerotial rot, alfalfa weevil, Magoura crassicauda, and so on. These pests did not injury the pear and persimmon tree. The occurrence amount of major pests on pear and persimmon tree did not affected by different surface management methods. But, biological diversity in soil enhanced significantly at hairyvetch culturing orchard. In pear orchard, diversity index at hairy vetch planting, grass planting and clean-tilled crops was 1.66, 1.16, 0.92, respectively.

The insecticidal activity of plant extracts by farmers' made on brown plant hopper(BPH), Nilaparvata lugens was evaluated in seedling bioassays. Mortality of single plant extract was very low but Japanese cypress and bamboo shoot extracts was high as 68% against BPH. The mixed extracts both Zanthoxylum piperitum and Ginko leaf extracts from brown rice vinegar was high mortality as 73%. Fermented pokeweed containing insecticidal soap was excellent mortality as 80% against BPH. Plant extracts from 95% alcohol had 4-fold higher mortality than that of water and vinegar. It suggested that plant extracts of Acorus gramineus, Melia Azedarach, Zanthoxylum piperitum, Chamaecyparis obtusa were high insecticidal activity against BPH.

Influence of aggregation pheromone trap on the distribution of egg parasitoids of *Riptortus pedestris* (Hemiptera: Alydidae) in soybean

Bishwo Prasad Mainali[1], Un Taek Lim[2]

[1]*Andong National University, Republic of Korea,* [2]*Andong National University, Republic of Korea*

Aggregation pheromone of Riptortus pedestris (Fabricius) (Hemiptera: Alydidae) attracts its egg parasitoids, Ooencyrtus nezarae Ishii (Hymenoptera: Encyrtidae) and Gryon japonicum (Ashmead) (Hymenoptera: Scelionidae). Distribution and composition of these egg parasitoids were investigated in a soybean field where aggregation pheromone baited traps were installed for two consecutive years (2010 and 2011). Three traps without/with aggregation pheromone were installed on the edge of soybean field in before/after design. Parasitism changes were assessed on non-viable host eggs released at distances of 9, 18, 27, and 36 m from the trap. Higher egg parasitism (1.5 to 2 times) and adult emergence (1.8 to 2.6 times) was found up to 18 m distance from trap installation point in the presence of pheromone. Relative parasitism of the two parasitoids was different by years, but was not affected by the pheromone installation.

Keywords:*Ooencyrtus nezarae, Gryon japonicum, host egg release, parasitism, conservational biological control*

The Effect of Light-emitting diodes Source and Quality on Occurrence of Aphid

Hae Ran Kim[1], Kyeong-Mi Lee[2], Jang-Mi Shin[3], Hoon-bok Yi[4], Young-Han You[5]

[1]Kongju National University, Republic of Korea, [2]Kongju National University, Republic of Korea, [3]Kongju National University, Republic of Korea, [4]Seoul Women's University, Republic of Korea, [5]Kongju National University, Republic of Korea

Light-emitting diodes are used as the principal artificial light source in plant factory. The light environment created by a combination of artificial lighting influences directly or indirectly performance of pests. Aphids are major pests in many crop and fruit species, because they remove plant assimilates induce galls and transmit plant viruses. Thus, we investigated the effect of different LED light source and quality on aphid behavior in the LED chamber system. The nine light treatments were combined in three colors LED, duty ratio and irradiation time ratio. T1, T2 and T3 were treated by red+blue LED light and each duty ratio was controlled by 100%, 99% and 97% respectively. T4, T5 and T6 were adjusted for irradiation time ratio of the red and blue LED per minute and were 2:1, 5:1 and 10:1 respectively. T7, T8 and T9 were treated by red+blue+white LED light and each duty ratio was controlled by 100%, 99% and 97% respectively. As a result, the number of occurrence of the aphids in mixed LED light treatments was much more than blue LED alone, and especially, red+blue mixed light treatment had more aphids than red+blue+white mixed light gradient. Also, the number of aphids increased with higher red:blue ratio and duty ratio.The nine light treatments were combined in three colors LED, duty ratio and irradiation time ratio.

Impact of resistance inducers for the management of late blight and sucking insects on Potato

Muhammad Usman Ghazanfar[1], Waqas Wakil[2], Yong Jung Kwon[3]

[1]University of Sargodha, Pakistan, [2]University of Agriculture, Faisalabad, Pakistan, Pakistan, [3]Kyungpook National University, Republic of Korea

Muhammad Usman Ghazanfar1, Waqas Wakil2, Yong Jung Kwon3 1 Department of Plant Pathology, University College of Agriculture, University of Sargodha, Pakistan 2 Department of Agricultural Entomology, University of Agriculture, Faisalabad, Pakistan 3 School of Applied Biology and Chemistry, Kyungpook National University, Daegu, Korea Abstract Pre-treatment of plants with chemical elicitors induces systemic resistance against plant pathogens and insect herbivores. The present study investigated the induction of defense responses and protective effects against Phytophthora infestans (Mont.) de Bary and sucking insects by the application of Salicylic acid (SA) and ?-aminobutrytic acid (BABA) under the green house conditions. Different dose rates of SA and BABA (2, 4 and 5 mM) were tested as foliage sprays. The application of both resistance inducers significantly suppressed the disease development 54.13% in case of SA and 67.47% in case of BABA by 15 days after inoculation with pathogen. The number and size of the lesions per plants were also greatly reduced by the application of treatments. Plants treated with BABA showed increased resistance against herbivory by aphids, thrips and whitefly with reduced fecundity of nymph, larvae and adults compared to SA treated plants. Changes in the activities of peroxidase and polyphenoloxidase were also studied. Potato plants treated with SA and BABA showed significantly higher peroxidase and polyphenoloxidase than water treated plants. From the present findings we speculate that metabolites produced as results of treatment with elicitors are responsible for protection against late blight and sucking insect pests and they can be used for successful disease/insect pest

Studies on standard setting and mass rearing of natural enemies; *Aphidius colemani* Viereck, *Nesidiocoris tenuis* (Reuter) and *Chrysoperla canea* (Stephens)

Eunhye Ham[1], Cheol Hak Kim[2], Young Cheol Choe[3], Jun Seok Lee[4]

[1]Osangkinsect Co., Ltd. Kyungpook National University, Republic of Korea, [2]Osangkinsect Co., Ltd., Republic of Korea, [3]National Academy of Agricultural Science, Republic of Korea, [4]Osangkinsect Co., Ltd., Republic of Korea

Worldwide, more than 125 species of natural enemies are commercially available for biological control. In Korea, commercial use of biological control has seen a very fast development during the past 15 years. Currently, about 10 companies produce more than 35 species of natural enemies. The success of biological control depends upon the standard setting and effective mass rearing of natural enemies. In this work, we have evaluated the effects of a standard setting and mass rearing of natural enemies (Aphidius colemani Viereck, Nesidiocoris tenuis (Reuter) and Chrysoperla canea (Stephens)), applied with different techniques. The mass rearing process should be done with the acceptable quality. The quality control programmers should be designed in order to obtain acceptable quality, not necessarily the possible quality.As a result of intensive cooperation between researchers and the biological control practitioners we will develop simple and reliable quality control programs, standard setting and mass rearing for natural enemies. It is expected that these developments will result in a rapid improvement of the biological control industry.

Superior defense systems in maize landraces: a potential pest management tool for smallholder maize farmers in Africa

Charles A.O. Midega[1], Amanuel Tamiru[2], Toby Bruce[3], John Pickett[4], Zeyaur Khan[5]

[1]International Centre of Insect Physiology and Ecology (icipe), Kenya, [2]International Centre of Insect Physiology and Ecology (icipe), Kenya, [3]Rothamsted Research, United Kingdom, [4]Rothamsted Research, United Kingdom, [5]International Centre of Insect Physiology and Ecology (icipe), Kenya

Maize (corn), Zea mays, is a major staple and cash crop for millions of smallholder farmers in Africa. However, its production is severely constrained by lepidopteran stemborers, including Chilo partellus (Swinhoe). Control of these pests is difficult due to the burrowing into the plant stem by the larval stages of the pest. Feeding on the maize by stemborer larvae leads to an emission of herbivore induced plant volatiles (HIPVs) that attract the pest's natural enemies. Here we report discovery of maize landraces that react to egg deposition by C. partellus by increasing emission of HIPVs that attract parasitic wasps against both egg and larval stages of the pest. There is also reduced attractiveness of the plants for subsequent oviposition by the moths. This trait however seems absent in elite commercial maize hybrids. This therefore implies a sophisticated defence strategy whereby parasitoids are recruited in anticipation of egg hatching. These findings suggest that indirect plant defence traits may have become lost during crop breeding and could be valuable in new resistance breeding for sustainable agriculture.

Study on resistance monitoring of major pests in rice to insecticides

Xiao Hu[1], Jianhong LI[2], Peng Lu[3], Xiaolei Zhang[4]

[1]Huazhong Agricultural University, China, [2]Huazhong Agricultural University, China, [3]Huazhong Agricultural University, China, [4]Huazhong Agricultural University, China

Rice stem borer (Chilo suppressalis), rice leaf folder (Cnaphalocrocis medinalis), and brown planthopper (Nilaparvata lugens) are three major pests on rice which heavily damage rice production annually in China. The resistance of three pests against insecticides were detected by topical application, leaf-dipping technique and rice stem-dipping method, respectively from 2006 to 2010 in Hubei province. The results showed that the Jianli population of rice stem borer had moderate levels of resistance to triazophos from 2007 to 2009. The rice leaf folder in this four field populations remained susceptible to abamectin with the LC50 values 0.26-1.24 mg/L, but the sensitivity of Zhijiang and Ezhou population to chlorpyrifos reduced year after year, indicating the rice leaf folder produced a certain resistance to chlorpyrifos from 2008 to 2010. The resistance of brown planthopper produced high level of resistance to imidacloprid in Hubei province from 2006 to 2010, some reached an extremely high level of resistance (389.19-fold). The resistance level and the resistance development speed of brown planthopper to buprofezin were discrepant among seven populations from 2007 to 2010, and some reached a high level of resistance. Gongan population developed high level of resistance to buprofezin (52.1-fold).

Developmental Control of brown planthopper *Nilaparvata lugens* (Hemiptera: Delphacidae) by ingestion of dsRNA of arginine kinase gene

Miao Yuan[1], Jianhong Li[2], Xinru Wang[3], Depan Cao[4]

[1]Huazhong Agricultural University, China, [2]Huazhong Agricultural University, China, [3]Huazhong Agricultural University, China, [4]Huazhong Agricultural University, China

RNA interference (RNAi) is a technological breakthrough that has been developed as a powerful tool for studying gene function and for the highly targeted control of insect pests. The effect of using a feeding-based RNAi technique to silence the Arginine kinase (AK) gene in Nilaparvata lugens was examined. Arginine kinase participates in cellular energy metabolism in invertebrates, which is analogous to the creatine kinase reaction. As s member of the phosphagen kinase family, it buffers cellular ATP levels by catalyzing the reversible phosphoryl transfer between ATP and arginine, leading to the production of phosphoarginine and Mg2+ADP. The completely coding region of Nilaparvata lugens ak is 1071 bp and encodes a protein of 357 amino acids. According the part of ak gene sequence which contain the active motif CPTNLGT, the gene specific primers were designed to amplify the sense strand and anti-sense strand DNA of ak gene. Because the designed primers include T7 promotor, the sense strand and anti-sense strand DNA of ak gene could be transcribed to dsRNA in vitro. Then, the purified dsRNA of ak gene was ingested into Nilaparvata lugens by artificial diet. The preliminary results show that sustained feeding the artificial diet contained ak dsRNA could killed 70% Nilaparvata lugens after 7 days. At the same time, the plant expression vector pds1301-ak that can express ak dsRNA was constructed and transformed the pds1031-ak vector into Agrobacterium tumefaciens.

Resistance monitoring of *Plutella xylostella* to insecticides in central China

Hao Qiu[1], Jianhong LI[2], Daofen Bi[3], Fengna Yao[4], Hong You[5]

[1]Huazhong Agricultural University, China, [2]Huazhong Agricultural University, China, [3]Huazhong Agricultural University, China, [4]Huazhong Agricultural University, China, [5]Huazhong Agricultural University, China

Diamondback moth (DBM), Plutella xylostella L., is the most destructive pest on brassicaceae throughout the world. Because of the overuse of traditional insecticides, DBM's resistance to insecticides has attracted the world's attention. In this study, leaf-dipping method was used to monitor resistance of four field populations of DBM in central China (Wuxue, Yichang, Luoyang and Yueyang) to 10 kinds of insecticides (diafenthiuron, spinosad, chlorfenapyr, chlorfluazuron, cartap, Bt, indoxacarb, beta-cypermethrin, abamectin and tebufenozide) from 2008 to 2010. The results showed that resistances of four field populations of DBM in central China to beta-cypermethrin and Bt were in high to extremely high level, with resistant ratio ranged from 67.70- to 257.31-fold, 113.88- to 713.17-fold, respectively. Four field populations had moderate to high level resistance to chlorfluazuron, with resistant ratio ranged from 16.79- to 133.36-fold. Resistant ratios of four field populations to abamectin and tebufenozide ranged from 15.29- to 47.00-fold, 15.84- to 45.92-fold, respectively, while resistant ratios of field populations from Yueyang to cartap and indoxacarb, ranged from 11.30- to 26.45-fold, 10.13- to 12.88-fold, respectively, all indicated that resistances were in moderate level. Results also showed that field populations, collected from Luoyang, Wuxue and Yichang, were susceptible or had low level resistance to cartap, indoxacarb, diafenthiuron, spinosad, and chlorfenapyr. Field population of DBM from Yueyang had low level resistance to diafenthiuron, spinosad, and chlorfenapyr.

Comparative vertical and horizontal dispersion behavior of *Trichogramma brassicae* in the maize and rice fields

Gholamhossein Gharekhani[1], Samaneh Soltantoieh[2], Ali Mehrvar[3]

[1]University of Maragheh, Iran, [2]University of Maragheh, Iran, [3]University of Maragheh, Iran

Insect parasitoids have to disperse to locate host and host habitat. The parasitoid wasp Trichogramma brassicae is a dominant as well as the most important species of Trichogramma in Iran. For study the behavior of this parasitoid in the rice and maize fields, it is reared on the eggs of the grain moth. Wasps were marked using fluorescent powder and released from a central point. Parasitoids dispersal was studied using trap cards includes the eggs of the intermediate host at 2, 5, 9, 12, 18 and 25 m distanced from the central point and 30, 100 and 130 Cm above the ground on rice and 20, 50 and 100 Cm on maize fields. Trap cards were collected three days after releases and examined in the laboratory after six days. Analyses carried out using SAS software and GLM procedure. Results showed significant influence of heights, distances and the day after release as well as the crops. Mean comparison revealed different flight behavior of the parasitoids on different crops since the highest parasitism occurred in the medial heights in rice and in the first and third heights in maize. In addition, parasitism rates were not significant in 2-5 m and 2-9 m distanced from releasing point in rice and maize respectively, while the results at other distances were significant in both fields. Hence, vertical and horizontal dispersion of the parasitoid is influenced by the crop architecture, height and distance.

Sequential Sampling Plans for Estimating Population Density of *Heliothis viriplaca* Hufnagel (Lep : Noctuidae) on Rain-Fed chickpea

Heidar Adldoost[1], Nouraddin Shayesteh[2]

[1]West Azarbaijan Reasearch Center for Agriculture and Natural Resource, Iran, [2]Islamic Azad University, Mahabad Branch, Iran

The Pod borer, Heliothis viriplaca Huf, is considered one of the major insect pests of chickpea in Iran. Crop losses due to this pest can be substantial and may be prevented or reduced, by implementing an integrated pest management program (IPM). The success of IPM programs depends on good monitoring, so that sampling could be a key element. 28 chickpea fields (Kabuli Type) at the elevations of 1300 ? 1800 meter, were sampled during 2010 and 2011 in different localities of West Azarbaijan province of Iran. A 1 × 0.5 square meter sampling frame was used for sampling the H. viriplaca larvae. The maximum larval population (3.26 larvae/square meter) was recorded in Somaibradost district of Orumieh. However, the minimum larval population (0.14 larvae/square meter) was recorded in central district of Tekab. Taylor's power law regression model was used to describe the spatial distribution of larvae. B-value was 1.342 and indicated chickpea pod borer were aggregated in rain-fed chickpea. A fixed precision sequential sampling plan was developed using the parameters of Taylor's power low generated from the total number of larvae in the sampling frame. Stop lines were estimated at two precision levels (D) of 0.1 and 0.25. High-precision sampling plans generally necessitated impractical sample sizes, and thus we present a relatively low-precision level plan (SE/mean = 0.25).

Toxicity of chlorpyriphos and fenpropathrin to *Habrobracon hebetor* (Hymenoptera: Braconidae)

hajar Faal-mohammadali[1], Ali-asghar Seraj[2], Khalil Talebi-Jahromi[3]

[1]Chamran University, Iran, [2]Chamran University, Iran, [3]Chamran University, Iran

Habrobracon hebetor (Say) is a larval ectoparasitoid of several species of Lepidopteran pests including Tomato fruitworm (Helicoverpa armigera Hubner). The lethal effects of chlorpyriphos and fenpropathrin, which are overused in tomato production, were evaluated on the larval, pupal, and adult stages of the parasitoid H. hebetor in the laboratory. Dose-response bioassays have carried out on immature and adult stages by using dipping and contact residue methods, respectively. The results indicated that the slopes of dose-response line for all treatments were positive. This cleared that there was an increase in mortality regarding an increase in concentration for both insecticides. Comparative evaluation of the slope values of the three probit lines showed that the slope of the adult stage treated with chlorpyriphos and pupae treated with fenpropathrine are higher than the slope of the others. The slope value of the above treatments suggested that chlorpyriphos is more toxic to H. hebetor. The LC50 of chlopyriphos for three development stages (larvae, pupa, adult) was 0.18, 9.95, 2.91 mg AI L-1, respectively and the LC50 of fenpropathrine for three development stages was 1.80, 20.76, 12.44 mg AI L-1, respectively. The recommended concentrations for chlorpyriphos and fenpropathrine are 408 mg AI L-1 and 200 mg AI L-1, respectively. The LC50 of chlorpyriphos varied from 40 to 2000 times less than the recommended rate and 10 to 100 times less for fenpropathrine treatments on different life-history stages. So, the application of these insecticides is not recommended when this parasitoid is released against the pests.

The Importance of the Parasitoid *Bracon hebetor* Say and the Pheromone Traps for Controlling *Ephestia* Spp in the Date Store

Ayad Ahmed Ridha AL-Taweel
Ministry of Science adn Technology, Iraq

The moth insects fig moth, Ephestia cautella, raisin moth, E. figulilella and carob moth, E. calidella, infest dates in date warehouses and orchards, this infestation was the main problem facing date trade in Iraq especilly after inhibiting using methyl bromide as an fumigant in the world, because it appeared to be Ozone depleting agentand carcinogenic agent. the results of using the parasitoidBracon hebetor and the pheromone traps in controllingmoth insects mentioned above were proved to be highly efficient in preserving date when they used together in the simulsted date warehouses in governorates:Baghdad, Karbala and Babylon for five months, the percentage of preserving dates were 91.6, 96.8 and 85.9% respectively, in comparison with 80.7 , 76.2 and 73.8% respectively, in the date warehouses in which the pheromone traps used only and with 70.2, 62.5 and 53.2%respectively , in the control date warehouses. These results suggest that the parasitoid B. hebetor and the pheromone traps should be recommended to be used for controlling moth insects mentioned above.

Parasitism of *Heliothis viriplaca* Hufnagel (Lepidoptera: Noctuidae) larvae by *Banchopsis crassicornis* Rudow (Hymenoptera: Ichneumonidae) in rain-fed chickpea

Heidar Adldoost[1], Nouraddin Shayesteh[2]

[1]*Western Azarbaijan Province Research Center for Agriculture and Natural Resource, Iran,* [2]*Islamic Azad University, Mahabad Branch, Iran*

Chickpea pod borer, Heliothis viriplaca Huf is a significant insect pest of chickpea in the south west Asia. A survey was carried out during 2008-2009 in the rain-fed chickpea fields of Western Azarbaijan province of Iran, to determine the parasitoids associated with the first or second instars larvae. First or second instars larvae were collected from the fields and fed on chickpea soaked seeds or on tender leaves inside glass tubes for emerging parasitoids. Results revealed that naturally parasitism of the larvae by Banchopsis crassicornis Rudow was considerable. Maximum parasitism (15.83%) was recorded in Somai Bradost district and the minimum (6.83%) was recorded in the Central district of Orumieh. Parasitized larvae continued feeding in the laboratory and developed to four or five instars inside the tubes. They stopped feeding a day prior to the emergence of the parasitoid from their bodies. In the laboratory conditions, none of the emerged larvae could enter the soil to form cocoons and all died. So that emerged larvae were warped in cotton and replaced in glass tubes. They readily formed brown spindle-shaped cocoons within 24 hours. The cocoons were kept for the emerging of adult insects. In field conditions, adult insects appeared in June, but in the laboratory conditions the adults, emergence took place in winter. The parasitoid had only one generation per year. B. crassicornis is distributed in Africa, Europe, Middle East and Caucasus and this is the first record from Iran. Also H. viriplaca is the new host recorded for this species.

Study on synergistic effects of henna in enhancement of pathogenicity of *Bacillus thuringiensis* Berliner on third and fourth instars larvae of Colorado potato beetle, *Leptinotarsa decemlineata* (Say)

Akbar Ghassemi-Kahrizeh[1], Nouraddin Shayesteh[2]

[1]*Islamic Azad University, Mahabad Branch, Iran,* [2]*Islamic Azad University, Mahabad Branch, Iran*

In this Study the synergistic effects of henna powder in enhancement of pathogenicity of Bacillus thuringiensis var. tenebrionis serotype H8a, 8b and Bacillus thuringiensis var. kurstaki strain EG2424 on 3rd and 4th instars larvae of Colorado potato beetle, Leptinotarsa decemlineata (Say) (Col.: Chrysomelidae), was evaluated. Combination of 3 concentrations of henna powder (3000, 4000 and 5000 ppm) with bacteria (500 and 1000 ppm for 3rd and 4th instars larvae, respectively) was used against 3rd and 4th instars larvae in completely randomized plot design in laboratory conditions. The results revealed that there was a remarkable synergistic effect of henna powder on B.t. efficiency. The 3rd instars larval mortality for mixture of B.t. var. tenebrionis (500 ppm) with henna (5000 ppm) was 72.5% after 6 days, however the mortality of larvae treated with B.t. var. tenebrionis (500 ppm) alone was 17.5% in this time. The mixture of B.t. var. kurstaki (500 ppm) with henna (5000 ppm) had caused 85% mortality in the 3rd instars larvae during 6 days. This concentration of B.t. var. kurstaki produced 22.5% mortality on this larvae. The mortality for 4th instars larvae treated with B.t. var. tenebrionis (1000 ppm) was 12.5% after 6 days, however this rate for 4th instars larvae treated with mixture of B.t. var. tenebrionis (1000 ppm) and henna (5000 ppm) was 47.5% in this time. The mortality of 4th instars larvae treated with mixture of B.t. var. kurstaki (1000 ppm) with henna (5000 ppm) was 3.4 times as much of the mortality of fourth

Study on morphological indices of Colorado potato beetle, Leptinotarsa decemlineata (Say) in west Azerbaijan province

Akbar Ghassemi-Kahrizeh[1], Nouraddin Shayesteh[2]

[1]Islamic Azad University, Mahabad Branch, Iran, [2]Islamic Azad University, Mahabad Branch, Iran

The Colorado potato beetle, Leptinotarsa decemlineata (Say), is a serious pest of potato, Solanum tuberosum L. worldwide. In this study, morphological indices of different biological stages of the Colorado potato beetle, Leptinotarsa decemlineata (Say) were evaluated in west Azerbaijan province. Weight, length and width of body for male and female adults, weight and length of body and head capsule diameter of different instars larvae, weight and length of pupae, egg length and number of egg in each egg mass were measured. The highest of weight, length and width average of body for adults were observed for female with mean values of 178.8±6.756 mg, 11.535±0.099 and 6.887±0.052 mm, respectively. The least and highest larval weight were observed for 1st and 4th instars with mean values of 1.300±0.082 and 88.667±6.191 mg, respectively. Average of head capsule diameter for 1st, 2nd and 3rd instars larvae were measured 0.684±0.011, 1.131±0.075 and 1.682±0.133 mm, respectively. Average number of egg in egg masses was measured 29.064±1.323.

Control of eight species of important stored products pest insects with environmentally compatible compounds

GholamReza Sadeghi[1], Jafar Hosseinzadeh[2], Nouraddin Shayesteh[3]

[1]Faculty of Agriculture, Urmia University, Urmia, Iran, [2]Faculty of Agriculture, Urmia University, Urmia, Iran, [3]Islamic Azad University, Mahabad Branch, Iran

The toxicity of ozone and mixture of this gas with nitrogen, phosphine and carbon dioxide were evaluated under field conditions. In parallel experiments, the toxic impact of bran, sawdust, clay , flour and sayan® on eight important stored product insects Tribolium castaneum (Herbst), Sitophilus oryzae L., Oryzaephilus surinamensis (L.), Rhyzopertha dominica (F.), Lasioderma serricorne F., Cryptolestes ferrurgineus (Stephens), Callosobrochus maculatus (F.) and 3rd instar larvae of Plodia interpunctella (Hubner) was determined. The adults of T. castaneum, S. oryzae, O. surinamensis, R. dominica, L. serricorne, C. furrurgineus, C. maculatus and 3rd instar larvae of P. interpunctella were exposed either solely to nitrogen or as a mixture with phosphine and ozone, carbon dioxide. These experiments were carried out either in empty storehouse or in the storehouse contained foodstuffs, such date, wheat and rice, respectively. The toxicity of the gases was determined after 24 h of exposure. Cononcomitantly with these trials, the lethal impact of ozone on the S. oryzae and O. surinamensis in different depths of rice, wheat and date was estimated as well. The results of empty storehouse tests revealed that, the mixture of nitrogen with phosphine caused 84.73% mortality response on S. oryzae. In similar experiments in the presence of foodstuffs the highest mortality rates were occurred on S. oryzae and P. interpunctella 3rd instar larvae in the depths of 30, 35 and 40 cm in date.

Resistance of different grape cultivars to grape erineum mite, *Colomerus vitis* (Acari: Eriophyoidae) in laboratory conditions

Saeid JavadiKhederi[1], Mohammad Khanjani[2], Babak Zahiri[3]

[1]Bu-Ali Sina University, Iran, [2]Bu-Ali Sina University, Iran, [3]Bu-Ali Sina University, Iran

The Grape Erineum Mite (GEM), Colomerus vitis Pagenstecher, is a serious pest of grape orchards (Vitis vinifera L.) in western Iran and sometimes causes a considerable damage to the crop. Initial observations in Hamedan showed the different levels of damage on different vine cultivars. Therefore the resistance of ten vine cultivars including White Thompson seedless, Red Thompson seedless, Fakhri, Yaghuti, Asgari, Muscat Gordo, Khalili, Flame seedless, Gazne and Shahani to GEM was examined to determine the potential use of resistant cultivars in pest management programs. The study was carried out under laboratory conditions at a temperature of 25±1°C, 65±5% R.H. and a photoperiod of L16: D8 h using pot disk method. Muscat Gordo, Gazne and White Thompson seedless cultivars with 100.4±0.45, 95.5±0.77 and 87.4±0.64 mite per leaf were shown the lowest and Shahani, Flame seedless and Yaghuti with 20±1.23, 24.2±1.24 and 24.7±2.15 mite per leaf showed the highest feeding repellency to the GEM, respectively. The highest oviposition rate was observed on M. Gordo and Gazne with 148.31±1.26 and 129.3±2.26 egg per leaf, respectively, and the lowest on Shahani with 10±1.37 egg per leaf. Our results showed that infested and non-infested leaf area of Shahani was not significantly different. Moreover, Shahani and Yaghuti cultivars had the highest bristle-like trichome density, whereas, M. Gordo and Gazne had the highest hair-like trichome density. According to the obtained results, Shahani and Yaghuti had the highest and M. Gordo and Gazne had the lowest resistance level to the GEM.

Total phenol and o-dihydroxy phenol profiles of black gram (*Vigna mungo* (L.) Hepper) genotypes infested by *Bemisia tabaci* (Gennadius) (Hemiptera: Aleryrodidae)

Gaurav Kumar Taggar[1], Ranjit Singh Gill[2], Anil Kumar Gupta[3], Sarvjeet Singh[4]

[1]Punjab Agricultural University, Ludhiana, India, [2]Punjab Agricultural University, Ludhiana, India, [3]Punjab Agricultural University, Ludhiana, India, [4]Punjab Agricultural University, Ludhiana, India

The principal limiting factor affecting production of black gram in northern India is whitefly, Bemisia tabaci (Gennadius) which causes direct injury by extracting sap from the plant tissue. The present study focused on deciphering comparative differences in total phenol and o-dihydroxy phenol (ODHP) profile of nine genotypes of black gram challenged by whitefly feeding. Total phenols and ODHPs were estimated from leaf samples collected at 30 and 50 days after sowing from whitefly infested and uninfested plants. Oviposition preference, nymphal and adult development of whitefly was also evaluated under screen house conditions. Correlation studies relating leaf content of black gram phenolics from different genotypes with whitefly population were also worked out. Biochemical analysis of black gram genotypes revealed that moderately resistant genotypes NDU 5-7 and KU 99-20 recorded higher per cent increase in their total phenol and o-dihydroxy phenol contents contents both at 30 and 50 DAS under whitefly stress conditions as compared to non-stressed plants. Total phenols and o-dihydroxy phenols showed significant negative correlation with whitefly population (nymphs and adults) suggesting that enhanced activities of these biochemicals may contribute to bioprotection of black gram plants against B. tabaci infestation. Hence, for developing tolerant varieties of black gram against whitefly, genotypes possessing higher total phenol contents can be selected for selection of desirable genotypes in whitefly resistance breeding programmes. Comparatively higher level of resistance in genotypes NDU 5-7 and KU 99-20 can serve as base for genetic improvement of black gram focusing on the development of resistant varieties to whitefly.

Insecticide resistance in Western flower thrips, *Frankliniella occidentalis* Pergande (Thysanoptera: Thripidae), on glasshouse cucumbers in Republic of Moldova.

Elena Moontean[1], Mihail Batco[2], Igor Yazlovetsky[3]

[1]Institute for Plant Protection and Ecological Agriculture, Moldova, Republic of, [2]Institute for Plant Protection and Ecological Agriculture, Moldova, Republic of, [3]Institute for Plant Protection and Ecological Agriculture, Moldova, Republic of

Introduction: Western flower thrips (WFT), Frankliniella occidentalis, is the dangerous pest of vegetable and ornamental crops in the glasshouses in many countries. In Moldova it episodically appears on vegetable crops in glasshouses. Mass reproduction of WFT was observed in 1996 on tomato [Verderevskaea et al., 1996] and in 2004 on cucumber [Moontean, 2004]. We studied the sensitivity of pest population to all four insecticides which are registered in our country for use in glasshouses: pyrimiphosmethyle (Aktellik, 50% EC), cypermethrin (Arrivo, 25% EC), imidacloprid (Confidor, 20% EC), and thiametoxam (Aktara, 25% WP). Methods: The study was carried out during 2004-2008 years. The sensitivity of thrips females to insecticides was estimated in the laboratory by the method of pest's settlement on insecticide-treated bean leaf discs. The median lethal concentrations of insecticide were determined by probit analysis and the rates of resistance were calculated. Results: WFT population collected on cucumbers was resistant to pyrimiphosmethyle (83x), cypermethrin (1700x) and imidacloprid (3x). The comparison of recommended and sublethal concentrations (LC95) of these insecticides has shown that they are not effective against F. occidentalis. The most toxic for thrips is thiametoxam. Conclusions: Studied WFT population is high resistant to organophosphate and pyrethroid insecticides. The resistance to imidacloprid develops in this population too. This leads to the need to expand the list of insecticides used against thrips in a covered ground. The number of insecticide treatments can be reduced by means of alternative methods of thrips control as the application of blue sticky traps with semiochemicals.

Effect of sublethal doses of spiromesifen, spirotetramat and spirodiclofen on fecundity and fertility of female adults of *Tetranychus urticae* Koch (Acari: Tetranychidae)

Mir Jalil Hejazi[1], Marzieh Amizadeh[2], Ghasem Askari Saryazdi[3]

[1]*University of Tabriz, Iran,* [2]*University of Tabriz, Iran,* [3]*University of Tabriz, Iran*

Two spotted spider mite is an important pest of many agricultural and ornamental plants worldwide. Spirotetramat, spiromesifen and spirodiclofen are new pesticides with novel modes of action and low environmental risks. Sublethal effects of these compounds were assessed on two-spotted spider mite in laboratory. Up to 24h old adult females were placed on leaf discs treated with sublethal concentrations (LC10 or LC25). LC10 of spirodiclofen, spiromesifen and spirotetramat were 0.05, 0.5 and 7.7 mg ai/l, respectively. LC25 of these compounds were 0.36, 3.3 and 19 mg ai/l, respectively. Twenty four hours after exposure to treated discs, 20 females showing no visible symptoms of poisoning were transferred to untreated leaf discs. The leaf disks were changed daily for up to five days. The number of eggs laid during this period was recorded. At the end of 24 h exposure period, the survival rate was 0.96 in controls; and 0.83, 0.93 and 0.83 in females treated with LC10; and 0.76, 0.83 and 0.76 in females treated with LC25 of spirodiclofen, spiromesifen and spirotetramat, respectively. The survival rate was decreased in all treatments at end of five days. Total number of eggs laid per female decreased in all treatments compared with controls. The average number of eggs/ female/ day was 2.6 in controls; and 1.22, 1.80, and 1.64, in females treated with LC10; and 1.61, 1.87 and 1.49 in the females treated with LC25 of spirodiclofen, spiromesifen and spirotetramat, respectively. Egg hatching rate was slightly lower in treated females compared with controls.

Lethal temperature for Japanese termite, *Reticulitermes speratus*, in infested wood using microwave energy

Sang Jae Suh[1], Jinseo Kim[2], Yong Jung Kwon[3]

[1]Kyungpook National University, Republic of Korea, [2]Kyungpook National University, Republic of Korea, [3]Kyungpook National University, Republic of Korea

Thermal death kinetics was examined to develop a heat treatment method to control the Japanese termite, Reticulitermes speratus, in wood packing materials for export goods. To determine the feasibility of microwave irradiation as an alternative treatment, we performed laboratory experiments on the blocks (200x200x250mm) of Canadian hemlock artificially infested with live termite workers with subsequent 2.45GHz microwave energy irradiation. The 100% mortality of treated termites was achieved above 55℃ of the measured wood temperature, regardless of irradiated time. All measurement points in the blocks reached 55℃ within 67-718 seconds with microwave irradiation by wood weight. We need further experimental verification, but commercial microwave (2.45GHz) treatment is a feasible alternative to conventional heat treatment to control Japanese termite on the wood packing materials for export goods.

Model development by control technique of natural enemy on the insect pest in cucumber greenhouses in Korea

Hyeong Hwan Kim[1], Myoung Rae Cho[2], Taek Jun Kang[3], Sung Jun Ahn[4], Sung Wook Jeon[5], Hae Woong Park[6]

[1]National Institute of Horticultural & Herbal Science, Republic of Korea, [2]National Institute of Horticultural & Herbal Science, Republic of Korea, [3]National Institute of Horticultural & Herbal Science, Republic of Korea, [4]National Institute of Horticultural & Herbal Science, Republic of Korea, [5]National Institute of Horticultural & Herbal Science, Republic of Korea, [6]National Institute of Horticultural & Herbal Science, Republic of Korea

Aphis gossypii, Aulacorthum solani, Tyrophagus neiswanderi, Frankliniella occidentalis, and Palpita indica are the important pest species on cucumber greenhouse culture in Korea. When tested with natural enemies, they were successfully controlled in cucumber greenhouses forcing and semi-forcing cultured between December and March. For A. gossypii control, banker plants were planted at a rate of 2 pot per 330 m2. Aphidius colemani and Propylea japonica were released at a rate of 0.8 mumy per m2 and 0.2 larva per m2, respectively. For A. solani control, P. japonica was used at a rate of 0.2 larva per m2. Hypoaspis aculeifer and Amblyseius cucumeris were combined at a rate of 15.2 and 38.0 nymphs and adults per m2, respectively, for T. neiswanderi control while three natural enemies including H. aculeifer, A. cucumeris, and A. swirskii were combined at a rate of 15.2, 38.0, and 18.9 nymphs and adults per m2, respectively, for F. occidentalis control. Entomopathogenic nematodes (Steinernema carpocapsae GSN1 strain) were sprayed 2-4 times at a rate of 30,000 Ijs per m2 for the control of P. indica larvae.

Occurrence of *Helicoverpa armigera* (Lepidoptera: Noctuidae) in Sindh, Pakistan

Mansoor Ali Shah
university of sindh, Pakistan

Helicoverpa armigera (American bollworm) is major lepidopteron pest of cotton and other crops such as tobacco, chilies, cucurbits, pea, maize etc. Present study for occurrence of Helicoverpa armigera carried out in four cotton growing localities of Sindh, Pakistan (Saeedabad, Hala, TandoAllahyar and Jamshoro), during 2008, 2009 and 2010. We have observed population of Helicoverpa armigera by Sex pheromones traps for moth collection and by field observation for damage %. During present study it is observed that Helicoverpa armigera found only in Hala locality and it was not found in other three localities. Highest moth population and infestation recoded in month of August September 2008, 2009 and 2010. Presence of Alternative host plants (Pea, maize, and Cucurbits) and thick vegetation throughout year are the main cause for occurrence of Helicoverpa armigera in Hala locality.

Management of mango hoppers *Idioscopus* spp. and *Amritodus* spp. (Cicadellidae: Hemiptera)

Abraham Verghese[1], Suresh Devi Thangam[2], G.Thimmaegowda Geetha[3]

[1]Indian Institute of Horticultural Research, India, [2]Indian Institute of Horticultural Research, India, [3]Indian Institute of Horticultural Research, India

Mango is seriously affected by several species of Cicadellids. The important species are Idioscopus nitidulus Lethierry, I. clypealis Lethierry, I. nagpurensis Pruthi, Amritodus atkinsoni Lethierry, and A. brevistylus Viraktamath. Hoppers on mango are widespread in Asia. The loss is due to the sap-feeding by adults and nymphs on flowers and shoots, which results in poor fruit-set and photosynthesis inhibition due to sooty mold on leaves. This yield loss ranges from 30 to 87%. Inadequate control leads to sooty mold staining the fruits reducing the commercial value. Studies at the Indian Institute of Horticultural Research, Bangalore, Karnataka, India showed that imidacloprid 200SL @ 0.25ml/litre of water as spray at early panicle emergence gave 100% control. Azadirachtin 0.03%@ 2ml/litre of water, neem soap @10gm/litre of water, suspension of Beauveria bassiana (MycoJaal)@5ml/litre of water gave effective control when populations are <4/panicle or when organic management is warranted, or in case of recurrence of hoppers after the first intervention. These have been found to be safe to pollinators also during full bloom when pollinators are active spray of any kind is not recommended. Further it was found that yellow sticky trap was useful in predicting the population on the tree for management decisions based on the model y = 1.3427x2 - 3.8731x + 1.3031; R2=0.86. It was found that under organic orcharding the predator Isyndus heros Fabricius survived to keep a check on the hoppers. The above management has been validated from 2009-2012. This study was supported by ORP-Sucking Insects and NABARD.

A new technique to control and rejuvenate wood bored mango trees by *Batocera rufomaculata* (Fale) (Cerambycidae: Coleoptera)

Thippenahalli Narayanappa Shivananda[1], Abraham Verghese[2], Manjunath R Hegde[3], Amrik Singh Sidhu[4]

[1]Indian Institute of Horticultural Research, India, [2]Indian Institute of Horticultural Research, India, [3]Indian Institute of Horticultural Research, India, [4]Indian Institute of Horticultural Research, India

India ranks first in terms of area and production of mango (Mangifera indica) in the world. Mango stem borer (Batocera rufomaculata) is considered a major pest resulting in partial drying or death of the plant due to damage of vascular bundles and/or secondary infection of Ceratocystis sp. To combat this problem, we have developed a product namely sealer cum healer comprising of few medicinal herbs namely Aloe vera, Withania somnifera to help the regeneration of damaged tissues and essential nutrients to rejuvenate and overcome deficiency of nutrients. The affected portion of the tree is cleaned by chipping the bark and the larva is removed/killed. After cleaning, the sealer cum healer is mixed in water and filled to the tunnels/holes by bringing to dough consistency. The tree trunk up to three feet is swabbed with the slurry of our product to absorb through stem/bark for correction of nutritional deficiency. The results from more than 2,000 trees in south India treated with our product have suggested that the borer problem and gummosis were controlled and also nutritional deficiency corrected in a year after treatment. In conclusion, we report that the sealer cum healer can effectively control stem borer and gummosis resulting in vigor by overcoming nutritional deficiency. The loss across India due to this borer is about 18 to 25%. Normally economically bearing older trees are affected. A single tree saved is equivalent to a saving of US $ 5000. The cost benefit amounts to 1: >100/tree/year. Support by NHM/NABARD is acknowledged.

Popularizing IPM of oriental fruit fly (*Bactrocera dorsalis*) in mango through an area wide approach in India

Thippenahalli Narayanappa Shivananda[1], Abraham Verghese[2], Manjunath R Hegde[3], Amrik Singh Sidhu[4]

[1]Indian Institute of Horticultural Research, India, [2]Indian Institute of Horticultural Research, India, [3]Indian Institute of Horticultural Reserch, India, [4]Indian Institute of Horticultural Research, India

Oriental fruit fly is a major pest in several pockets of mango growing areas in India. IIHR being a premier Institute in the country has worked out an integrated pest management (IPM) schedule for its management. By following IPM the damage due to fruit fly was brought down to zero to five percent based on the trials conducted at multi locations in the country. The IPM consists of surveillance traps @ 8/acre, raking of soil below the tree, sanitation by destroying fallen fruits and application of bait splash (jaggery at 10% mixed with a mild toxicant) on the basal stem portions of tree at weekly intervals, when the fruits attain 60% maturity. This IPM was demonstrated through front line demonstrations (FLD) with the participation of farmers in nearly 57,000 acres, in area wide mode with the financial assistance of NABARD, Department of Biotechnology, National Horticulture Mission and ICAR, Govt. of India . The technology has been popularized in six districts of Karnataka, two districts of Andhra Pradesh and one district of Kerala in south India for the last three years. By implementing IPM, the damage has been controlled from 95 to 100%. Encouraged by the results, Governments of Odisha and Jharkhand have also implemented the IPM schemes in collaboration with IIHR. This IPM would lead to mitigation or fruit fly free regions in India besides enhancing yield by 30%. The cost benefit ratio was 1:.50. The trap technology was standardized with the collaboration of Imperial College London under DFID funding.

Evaluation of entomopathogenic fungi for the control of green peach aphid, *Myzus persicae*

Won Woo Lee[1], Tae Young Shin[2], Jae Bang Choi[3], Sung Min Bae[4], Yeon Ho Je[5], Byung Rae Jin[6], Soo Dong Woo[7]

[1]Chungbuk National University, Republic of Korea, [2]Chungbuk National University, Republic of Korea, [3]Chungbuk National University, Republic of Korea, [4]Chungbuk National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Dong-A University, Republic of Korea, [7]Chungbuk National University, Republic of Korea

The green peach aphid, Myzus persicae Sulzer, is an economically important pest for greenhouse crops, because they cause direct damage by feeding on plant nutrients and indirect damage as transmits many virus vectors. Moreover, the overuse of insecticide has resulting in resistance among green peach aphid population and environmental pollution. Thus, the development of entomopathogenic fungi has received increasing interest as part of integrated pest management strategies as aphid biocontrol agents. In this study, we report the screening result of pathogenic fungi for the control of green peach aphid. Initial screenings were performed using 347 isolates of putative pathogenic fungi from Korea soils. As results, 20 isolates of entomopathogenic fungi were isolated from cadavers of green peach aphid supporting fungal conidiation. These isolates were identified as three strains of Lecanicillium attenuatum, nine strains of Beauveria bassiana, one strain of Metarhizium anisopliae, one strain of Metarhizium flavoviride, five strains of Paecilomyces lilacinus, one strain of Aspergillus sp. by microscopic examination, genetic sequencing of the ITS region and Universally Primed PCR (UP-PCR). Based on the screening results, twenty isolates were tested for their pathogenicity against adult green peach aphid, cold activity, thermotolerance, UV-B irradiation on conidia. All fungal isolates were pathogenic to green peach aphid but mortality varied with isolates. These entomopathogenic fungi may be useful to develop eco-friendly insecticide to control green peach aphid.

Preparation and characterization of pheromone dispenser using nano materials

Sung Man Seo[1], Hu Sik Kim[2], Un Taek Lim[3], Woo Taik Lim[4]

[1]Andong National University, Republic of Korea, [2]Andong National University, Republic of Korea, [3]Andong National University, Republic of Korea, [4]Andong National University, Republic of Korea

The pheromone dispensers for Riptortus clavatus (Thunberg), Leptocorisa chinensis (Dallas), and Plautiastali (Scott) were synthesized using nano materials such as various divalent cations and hexadecyltrimethylammonium cation-exchanged zeolites A, X, and Y, MCM-41, and ETS-10. Each of pheromone component, (E)-2-hexenyl-(E)-2-hexenoate, (E)-2-hexenyl-(Z)-2-hexenoate, Myristylisobutyrate for Riptortusclavatus, 2-(E)-octadenyl acetate and octanol for Leptocorisachinensis, and methyl(E,E,Z)-2,4,6-decatienoate for Plautiastali, investigated maximum sorption capacity into/onto diverse materials by gas chromatography method. In case of all, various cation exchanged zeolites X and Y showed outstanding sorption contents comparison with other materials. In this work, we observed that the presence and absence of sorption sites and pore dimensions in nanoporous materials have the greatest effect on the rate of sorption, decreasing with decreasing pore diameter, and sorption sites for chemical interaction.

Effect of pyriproxyfen on some physiological aspects of the pistachio fruit hull borer, *Arimania comaroffi*, pupae

Marjan Bemani[1], Hamzeh Izadi[2], Kamran Mahdian[3], Mehdi Basirat[4]

[1]Vali-e-Asr University, Iran, [2]Vali-e-Asr University, Iran, [3]Vali-e-Asr University, Iran, [4]Pistachio Pests and Diseases Research Center, Rafsanjan, Iran

Pistachio fruit hull borer, Arimania comaroffi (Lepidoptera: Pyralidae), is one of the minor pests of pistachio trees, overwintering as pupa in silken cocoon in soil beside pistachio trees. In this study, effect of pyriproxyfen (an insect growth regulator), was investigated by measuring glycogen, glucose, lipid and protein contents of pupa. The last larval instar was exposed to pyriproxifen; the effect was studied in one week old pupa. Low molecular weight carbohydrate (glucose) as well as glycogen and lipid contents were measured by methods described by Warburg and Yuval (1996). Protein content of whole body was measured by Lowery method (Lowery et al., 1951). Glycogen content of treated pupae (3.11 mg/g fresh body weight) was significantly lower than control (8.51 mg/g fresh body weight).but no significant difference was observed between protein and lipid contents of treated pupa and control ($P>0.05$). Glucose content in pupae treated with pyriproxyfen (1.50 mg/g fresh body weight) was significantly different from control (2.99 mg/g fresh body weight). This study revealed that pyriproxyfen is able to significantly decrease carbohydrate level of treated pupa in relation to control.

Insecticidal effects of *Thuja occidentalis* (Cupressaceae) essential oil on *Tribolium confusum* Duval (Col.: Tenebrionidae)

Nouraddin Shayesteh[1], Jafar Hosseinzadeh[2], Shadi Delkhoon[3], Omid Panahi[4]

[1]Islamic Azad University, Mahabad Branch, Iran, [2]Faculty of Agriculture, Urmia University, Urmia, Iran, [3]Islamic Azad University, Urmia Branch, Iran, [4]Urmia University, Urmia, Iran

In order to find recyclable, environment friendly and easy accessible insecticides, the essential oils of Thuja occidentalis L. (Cupressaceae), was used against the adult stages of Tribolium confusum Duval (Col.: Tenebrionidae). Analysis of Thuja occidentalis L. essential oil used for insect fumigation by phase gas chromatography revealed the presence of 22 compounds including α-thujone (49.64%), fenchone (14.06%), and β-thujone (8.98%). The experiment was conducted in 6 replications using a completely randomized design of factorial experiment. The essential oil was prepared by water distillation method. Experiment was carried out at 30±2 °C and 60±5% R. H. under dark condition. Concentrations are included 0.00277, 0.00352, 0.00425, 0.005, 0.00574 µl/l air and a control (untreatment), after 24 h, respectively. At the concentration of 0.00648µl/l air essential oil of Tribolium confusum Duval, caused 100% mortalities of adults, respectively. A value of 50% lethal concentration on adults was 0.111601µl/l air for Tribolium confusum Duval, respectively.

Effects of Lufox on *Lobesia botrana* (Lepidoptera: Tortricidae) egg and larval stages

Jafar Hosseinzadeh[1], Nouraddin Shayesteh[2], Shadi Delkhoon[3], Omid Panahi[4]

[1]Faculty of Agriculture, Urmia University, Urmia, Iran, [2]Islamic Azad University, Mahabad Branch, Iran, [3]Islamic Azad University, Urmia Branch, Iran, [4]Urmia University, Urmia Branch, Iran

The effect of the chitin synthesis inhibitor Lufox was evaluated against different developmental stages of lobesia botrana Den. & Schiff. (Lepidoptera: Tortricidae). In the present study the effect of the Lufox on the egg and larval stages were examined. Eggs included one to four days and Larvae were examined, including age one to age five.High activity was observed against L. botrana eggs with greater effect on 1-d-old eggs than on the other age classes and on eggs treated by direct contact rather than those laid on a previously treated surface. Eggs laid by treated adults showed the same effects during development as eggs treated by contact or those laid on a trcated surface. Larvae that emerged that from treated eggs could not perforate grape berries. Administrated into the diet, Lufox had a larvicidal effect, resulting in similar LC50 values for different instars for eggs: 0.35 ppm for one day old eggs, 0.39 ppm for two day old eggs, 0.43 ppm for three day old eggs and 0.49 ppm for four day old eggs and resulting in similar LC50 values for different instars for larvae's: 0.34 ppm for first instars, 0.36 ppm for second instars, 0.38 ppm for third instars, 0.41 ppm for fourth instars and 0.43 ppm for fiiveth instars.

Interaction of *Bacillus thuringiensis* Berliner and the parasitoid, *Diadegma insulare* (Cresson) (Hym., Ichneumonidae) and diamondback moth, *Plutella xylostella* (L.) (Lep., Plutellidae)

Morteza Ebrahimi[1], Ahad Sahragard[2], Reza Talaei-Hassanloui[3]

[1]University of Guilan, Rasht, Iran, [2]College of Agriculture, University of Guilan, Rasht, Iran, [3]College of Agriculture and Natural Resources, University of Tehran, Karaj, Iran

The survival of adult of D. insulare and adult Plutella xylostella (L.) treated with Bt-honey solution and the effect of Bt on immature stages of Diadegma insulare (Cresson) within host larvae, P. xylostella (L.) were evaluated in laboratory conditions in a growth chamber at 25 ± 1C, 65±10%, relative humidity (RH) and 16 : 8 h (L : D) photoperiod. Diamondback moth and Diadegma insulare pupae were collected from cabbage fields in Karaj (Iran). Commercial formulation of Bt. (Biolep®, Bacillus thuringiensis var. kurstaki) was used in these experiments. The value of LC50 for third instar larvae of P. xylostella was 209.59 ppm. DBM's and Parasitoid's adult survival at field rate of Bt was not significantly different from that of control. Formation of parasitoid's pupae in Bt-parasitoid combined treatments was significantly lower than parasitoid lonely. The Bt-parasitoid combined treatment significantly increased mortality of larvae of parasitoid within DBM larvae treated with Bt. Mean percentage mortality of larvae of DBM in LC30 and LC50 concentrations of Bt. combined with parasitoid was approximately 100% that was significantly higher than control (using parasitoid lonely). Our results showed that B. thuringiensis don't kill adults of DBM and parasitoid but kills D. insulare larvae indirectly by killing susceptible hosts in which they are developing. Successful use of multiple biological control agents will depend on close monitoring of their compatibility in the field.

Abundance of the beneficial insect predator Laius venustus (Coleoptera: Malchiidae) in Sudan and risk of some commonly used insecticides on its population

Hayder Abdelgader
Agricultural Research Corporation, Sudan

The Melyrid beetle, Laius venustus was reported as an important natural enemy of the cotton Jassid (Jacobiasca lybica) and the cotton Whitefly (Bemisia tabaci) in Sudan. The abundance of the beneficial insect predator Laius venustus early in the cropping season 2004 was observed and surveyed on a groundnut field at the Gezira Research Farm (Wad Medani, Sudan). The predator appeared in large numbers in Mid-July and declined afterwards. During the survey similar numbers of adults of the predator were caught throughout the groundnut field. A relatively larger numbers were caught during mid-day compared to early in the morning. Dose-mortality tests with the most commonly used insecticides in Sudan were carried out. The results indicated a relatively higher toxicity of dimethoate and cypermethrin to field collected adults. Endosulfan was relatively safe to the tested beetles. Log dose ? Probit lines and the equations for each insecticide at different periods were determined. A susceptibility ratio based on the field recommended dosage rate was calculated

The application of insecticide against wires (*Agriotes meticulous*) at planting potatoes

Rakhmat Rasulov[1], Tulkin Ortikov[2], Toshniyoz Goziev[3]

[1]Samarkand Agricultural Institute, Uzbekistan, [2]Samarkand Agricultural Institute, Uzbekistan, [3]Samarkand Agricultural Institute, Uzbekistan

The protection of the yield of potatoes from different soil pests is of great importance from the scientific practical point of view here are such pests as larvae of beetles click (wires) false wires different types cockchafers, varmints larvae, stalk-grawing trowels (winter and gamma trowels and others). The scientific hypothesis and practice show that any water-soluable preparations (concentrates of emulsions, suspensions, colloidal and true solutions and others) applied in struggle against mentioned above soil pests, are absolutely perspectiveless because they are mainly contactable and available preparation of systematic effect don't give expected result owing to the characteristics of the environment (soil) in which these pests dwell. That is why the creation and application of powdery insecticides against soil pests is very actual/ For this purpose we have created the powdery preparation "Erdust", which combines 2 active matters at the expense of additional effect - phosphorus-organical compound any synthetic piretroids. After all-round prohibition of dusts DDT a GHCD there appeared the vital need for poundery preparations and such kinds powders were obtained for the first time. The researches were conducted according to generally accepted methodics and under conditions of field tests. It is ascertained that 2-times application of powderly preparation "Erdust" in the dozes: at planting potatoes -20-30 kg/ha and interrow processing -20-30 kg/ha fully exterminate the larvae of clicking-beetles (wirers). Its quality and the outer appearance of tubers improves.

The biological protection of tomatoes from broomrape with the help of *.Piytomyza orobanhia* Kalt

Rakhmat Rasulov[1], Toshniyoz Goziev[2]

[1]*Samarkand Agricultural Institute, Uzbekistan,* [2]*Samarkand Agricultural Institute, Uzbekistan*

Weeds-parsites cause considerably greater harm to plants-hosts, than the mast harmful no parasitical weeds independently from the degree of choking the sowings. Among weeds-parasites a special place is occupied by broomrape Which causes great damage to such agricultural crops as: tomatoes, tobacco, cabbages, pumpkins, carrots, sunflowers, peanuts and others. There exist several ways of struggle with broomrape Chemical (herbicides), biological (Front sight-fitomiza) organizational- economic (sowing resistant sorts) weeding and others. Taking into consideration mentioned above in 2010-2011 we conducted some experiments with testing different dozes of soil (triflurex) and exterminating effect (hurricane forte, round-up) herbicides on the plantings of tomatoes according to generally-accepted methodics. Besides, there were conducted experiments with growing and application natural enemy of broomrape front sight-fitomiza by methodics B.G.Bronshteign on the plantings of tomatoes in the neigh bouring farm (spatial isolation between experiments comprised 5-6 km). The first raising hopes results were obtained from the 2 exeriments. So, during experiments with herbicides there were revealed optimum dozes (round-up an triflurex), which allow to exterminate broomrape without any damage for tomatoe-plants. The biological effectiveness comprised (in average yearly) on herbicides comprised, accordingly 65,3 % and 63,5. During the experiment with front sight-fitomiza there were achieved positive results (biological effectiveness comprised in average yearly 55,2m %). Unfortunately the combination of chemical and biological methods of struggle against broomrape In one experiment didn't give positive results, owing to the sensibility of front sight-fitomiza to herbicides. But the work on this trend will be continued.

Keywords:*tomatoes,fitomiza,agricultural crops,broomrape Chemical*

Compatibility of *Lecanicillium longisporum* with acetamipride and imidaclopride under laboratory condition

Omid Panahi[1], Jafar Hosseinzadeh[2], Shadi Delkhoon[3], Nouraddin Shayesteh[4], Zahra Lak[5]

[1]Faculty of Agriculture, Urmia University, Urmia, Iran, [2]Department of Plant Protection, Faculty of Agriculture Science, Urmia University, Urmia, Iran., Iran, [3]Islamic Azad University, Urmia Branch, Iran, [4]Islamic Azad University, Mahabad Branch, Iran, [5]Islamic Azad University, Qom Branch, Qom, Iran

The entomopathogenic fungus Lecanicillium longisporum is one of the facultative insect pathogens with significant host range and host specifity. Conidia survival may be effected by environmental factors or by bio-pesticides and chemical products used to protect crop plants. Lack of attention to this point can be an obstacle to the development of fungi in the field to be considered. In this research compatibility of mentioned fungi with acetamipride and imidaclopride and effect of these insecticides on conidial germination and vegetative growth were studied. The formulations of insecticides were tested in tree concentration (mean concentration-MC, half MC and twice the MC). The study was conducted in Completely Randomized Design (CRD) with 4 replications. The results indicated that acetamipride and imidaclopride in half MC compatible with L. longisporum (isolate LRC190). However, based on the results imidacloprid compared acetamipride is adaptable with L. longisporum. This insecticides could be used simultaneously in low concentration with this entomopathogenic fungus in integrated pest management.

Keywords:*Lecanicillium longisporum, Entomopathogenic fungus, insecticides, Campatibility.*

Bionomic of *Tetranychus urticae* and *Scolothrips longicornis* on bean and cucumber

Hajar Pakyari
Islamic Azad University, Iran

ABSTRACT: Bionomics of two-spotted spider mite, Tetranychus urticae Koch, and Scolothrips longicornis Priesner was studied in the southeast of the Tehran province, Varamin from 11th July to 22th September 2010 on bean and cucumber. The mean population densities of the overall life stages of T. urticae and S. longicornis per leaf on cucumber (42.10 and 2.87, respectively) were significantly more than bean (6.18 and 1.32, respectively). The spatial distribution of T. urticae and S. longicornis was determined by the following two methods: Taylor's power law and Iwao's patchiness regression. The spatial distribution pattern of T. urticae and S. longicornis using Taylor's power law and Iwao's patchiness on cucumber was aggregated and on bean was random. The linear regression between the predator and prey population densities indicated a density-dependant predation by S. longicornis on T. urticae. Spatial distribution parameters of T. urticae and its predator can be utilized to outline a sampling program, estimate population density of these mites and efficiency of the predator for using in IPM programs.

Keywords:*Tetranychus urticae, Scolothrips longicornis, population density, spatial distribution, density depe*

Preliminary observation on the relation of BPH resistance and RRSV infection in rice entries carrying different BPH resistance genes

Xudong Zhu

China National Rice Reseach Institute, China

4 BPH resistance genes (Bph-1, Bph-3, Bph-10 and Bph-15) were regarded as BPH-resistant donors for hybrid rice breeding to cross with elite hybrid maintain or restorer lines in March 2011 in Hainan Island and 43 hybrid combinations (F1) were obtained. After germination, sprout seeds were sown in plastic box. All 1160 seedlings at 3-leaf stage of the 43 hybrid F1 were inoculated with BPH nymphs in laboratory in June 2011 in Hangzhou with a standard seed-box screen evaluation method. The offsprings of BPH caught from field on October 2010 and reared in rice seedlings of TN1 were used for infestation. Fifteen to twenty nymphs in the age of the 2nd to 3rd instar per seedling were infested. Though, the 4 BPH resistant genes are dominant, higher mortality rates of F1 plants overwhole were reached, the average survival rate of all lines holding the 4 resistant genes was only 18.97% with a range of 8.23 - 30.59%. The F1 plants survived from BPH infestation were transplanted into the field at 6- to 7-leaf stage. A high incidence of RRSV symptoms appeared in these plants in 2 to 3 weeks after transplanting. Partial of the RRSV infected plants could not enter the stage of panicle initiation, while others could reach this stage but could not fill seeds, only a few seeds could be harvested from some main stems of few small plants). The average percentage of plants with normal panicle filled (percentage of RRSV disease resistant) F1 plants was only 25.91%.

Effects of two isolates of *Beauveria bassiana* (Balsamo) Vuillemin on *Leptinotarsa decemlineata* (Say) (Col.: Chrysomelidae) larval stage

Mohammad Hossein Kazemi[1], Yasaman Shafighi[2], Yobert Ghousta[3], Jamshid Akbarian[4], Nouraddin Shayesteh[5]

[1]Tabriz Branch, Islamic Azad University, Tabriz, Iran, [2]Tabriz branch, Islamic Azad University, Tabriz, Iran, [3]Faculty agriculture, Urmia University., Iran, [4]Faculty agriculture, Urmia University, Iran, [5]Mahabad branch, Islamic Azad University, Mahabad, Iran

The primary damage of Leptinotarsa decemlineata (Say) (Col.: Chrysomelidae) is leaf feeding on potato. The fungus generally infects its host through the insect integument. Germ tubes from the conidia penetrate the cuticle of the insects surface body. Nowadays biocontrol by entomopathogenic fungi could be considered as a suitable alternative method to chemical insecticides or at least could be used as an alternative to the chemical insecticides. Beauveria bassiana is a fungus commonly found in soils worldwide. Insect's susceptibility varies in different strains of the fungus. In this study, two DEBI007 and IRAN1217C isolates of B. bassiana were used in pathogenicity trials on L. decemlineata second larval stage. Treatments were conducted at 25±1°C, 75 ± 5%RH and 16:8 light/dark. The mortality was counted daily. Revision surgery was 15 days and dead larvae were singled out for possible contamination incident within a week of wet filter paper were kept in Petri dishes. The contact and immersion method was applied against second instar larvae by suspension them in prepared pathogenic fungal. Application of spore suspension with the concentrations of 107, 3.1×107, 108, 3.1×108, 109 spores/ml of fungal isolates comprising two isolates of B. bassiana on Colorado beetle showed that LC50 belonging to IRAN1217C was 2.4 ×107 spores/ml, and in the case of DEBI007 the LC50 was 1.4×107 spores/ml. The results show that the fungi isolate DEBI007 has more insecticidal efficacy and effectively play its role in integrated pest control programs.

Investigation of lethal effect of Proteus and Movento on tobacco aphid (*Myzus nicotianae* Blackman) under greenhouse condition

Sepideh khalilolahi[1], Mahammad Hassan SafarAlizadeh[2], Nouraddin Shayesteh[3]

[1]Faculty of Agriculture, Urmia University, Urmia, Iran, [2]Faculty of Agriculture, Urmia University, Urmia, Iran, [3]Islamic Azad University, Mahabad Branch, Iran

Tabacco is one of the important agriculture and economical plants of the world and the income from its different products forms an important part of the national revenue of the countries which produce it. Myzus nicotianae is one of the dominate and most damaging of tobacco pests that in addition to sucking the sap, has a role in transmitting major viruses. Farmers use Primicarb, Imidiaclopride and Confider pesticides to prevent aphid damage although some degrees of resistance have been seen towards these pesticides. In this study the effect of two new insecticides namely, Proteus and Movento were investigated in order to use more effective insecticide and decreasing the times of poison spraying for the purpose of making the product more economical and maintaining the health of the farmers and the environment. In order to identify the poison level (LC50) of Proteus and Movento, bio-assessing experiments with spraying method on the wingless female adult under labratory conditions was carried out 25±5°c, 65±5% R.H, and 16:8 photoperiod of L:D. The results were analized by Probit method and Spss software. The results indicate that LC50 in 48 hours for Proteus and Movento was respectively 0.00034 and 0.00032. As the results indicate, Movento was more toxic on adult stage of Myzus nicotianae than Proteus.

Cloning and expression of a novel cry1 I gene from *Bacillus thuringiensis* isolates and its toxicity against *Myllocerus undecimpustulatus undatus* Marshall (Coleoptera : Curculionidae) and *Helicoverpa armigera*

H.M.Mahadeva Swamy[1], Ramasamy Asokan[2], Geetha G Thimmegowda[3], Nagesha S N[4], Riaz Mahmood[5], Dilip K Arora[6]

[1]Indian Institute of Horticultural Research(IIHR), India, [2]Indian Institute of Horticultural Research(IIHR), India, [3]Indian Institute of Horticultural Research(IIHR), India, [4]Indian Institute of Horticultural Research(IIHR), India, [5]Kuvempu University, India, [6]NBIAM, India

six isolates of Bacillus thuringiensis from Andaman and Nicobar Islands which were previously characterized by PCR analysis for the presence of Coleopteran active cry genes were used for Cry1I full length gene amplification. A 2.16-kb DNA fragment of Cry1I gene was PCR amplified, cloned in expression vector pQE 80 L, and then used for transformation of E. coli M15 cells. The optimum expression was obtained with 1 mM IPTG at 370C for 3 h. The sequence of the cloned crystal protein gene showed almost complete homology with a Cry1I toxin gene from Bacillus thuringiensis var. kurstaki, with scattered mutations in the toxic region. The deduced sequence of the protein has homologies of 91.0% with Cry1I and Cry1Ia, and 98.0% with Cry1Ib.Cloning of this gene may help to overcome the increasing resistance of pests to currently used insecticides. Based on the results obtained, the PCR method may be a valuable and reliable tool for specific detection and identification of cry1I genes. The toxicity of Bt recombinant protein was determined against first instar larvae of Myllocerus undecimpustulatus undatus Marshall (Coleoptera: Curculionidae) and Adults; Helicoverpa armigera Hubner (Noctuidae: Lepidoptera) at 310µg/mL and 15.5µg/mL respectively. The novel cry1I gene will be an important resource in constructing genetically engineered bacteria and transgenic plants for biocontrol of insect pests and Bt based biopesticidal formulations, aiming to reduce the use of chemical insecticides.

An investigation on aphids (Homoptera) biodiversity of apple trees in Urmia region

Nouraldin Shayesteh[1], Hossein Ranji[2]

[1]Islamic Azad University, Mahabad Branch, Iran, [2]Iranian Research Plant Protection, Iran

Biodiversity inciudes the diversity of species and their abundance. Biodiversity of homopteran species of apple tree in Urmia region was determind by measuring the number and abundance of each species collected during 2010-2011. During 2010-2011, investigation, nine species belonging to two families were collected and identified as follows: Family: Aphididae Eriosoma lanigerum (Hausmann) Myzus persicae (Sulzer) Dysaphis plantaginea (Pass.) Dysaphis affinis (Mordv.) Dysaphis Devecta (Walker) Dysaphis brancoi (CB) Aphis fabae (Scop.) Aphis pomi (Dedeer) Family: Lachnidae Pterochloroides persicae (Cholodovsky)

Investigation of population fluctuations of sunn pest,s egg parasitoids (Hymenoptera; Scelionidae) and estimating parasitism rate in central regions of West Azerbaijan Province, Iran

Farnaz Shafaie[1], Shahzad Iranipour[2], Mohammad Hossein Kazemi[3], Esmaeil Alizadeh[4]

[1]Tabriz Branch, Islamic Azad University, Tabriz, Iran, [2]College of Agriculture, University of Tabriz, Tabriz, Iran, [3]Tabriz Branch, Islamic Azad University, Tabriz, Iran, [4]Agricultural and Natural Resources Research Centre, Urmia, Iran

Sunn pest (EurygasterintegricepsPuton) is the most important insect pest of wheat in Iran. This pest has numerous natural enemies within which egg parasitoids are undoubtedly the most important of them. In the survey population fluctuations and estimating parasitism rate of these insects were investigated in three regions of West Azerbaijan Province, Iran (Uremia, Naghadeh and Mahabad) in 2011. The egg traps were used at weekly intervals in fields. The parasitoids emerged from the traps were identified. Overal five species including Trissolcusgrandis(Thomson), T. djadeshko(Ryachovski), T. rufiventris (Mayr), Ooencyrtusfecondus(Ferriere) and O. teleminocida(Vassiliev). T.grandiswas the most common species followed by T.djadeshkoin all regions. Estimating parasitism rate were investigated in three regions: Uremia 65%, Naghadeh 60% and Mahabad 58%.

Survey of the caused damage by the birds on the sunflower fields in different planting dates in west Azarbaijan

Esmaeil Alizadeh[1], Nouraddin Shayesteh[2]

[1]Agricultural and Natural Resources Research Center of West Azarbaijan. Urmia, Iran, [2]Islamic Azad University, Mahabad Branch, Iran

Birds are among the most important pests in the fields under sunflower cultivation that lead to huge annual losses of the crop. Out of the deleterious birds of sunflower fields, house sparrow (Passer domesticus) causes the most abundant damage in the regional fields of sunflower. The present investigation was carried out to evaluate house sparrow damage on sunflower cultures in the Agricultural and Natural Resource Research Station of Khoy since 2006 in a biannual research project. The main plots included four seeding dates with 15 day intervals and the accessory plots were three sunflower cultivars Alstar, Euroflor, and KSC43/128. The cultivars were seeded in the Khoy station and the rates of bird damages were calculated at the end of seed maturity period. Based on variance analyses of data, seeding dates and cultivars had highly significant impacts on sunflower yield and the damage rate. The highest protected yields were resulted from the first and the second seeding dates exceeding 2500 kg/ha. However, the most damage rates were also calculated with the first and the second seeding dates, respectively rated as 96% and 93%. The damage rate in the second year was higher than that in the first year. Among the tested cultivars, the hybrid Alstar was of the highest damage rate (92%), and two hybrids Euroflor and KSC43/128 were of the least damage rates.

The review of insecticidal activity and oviposition deterrence of essential oils from *Artemisia dracunculus* L and *Mentha piperita* L against *Callosobruchus maculatus* F.(Col.; Bruchidae)

Khadijeh Izakmehri[1], Moosa Saber[2], Samad Vojoudi[3]

[1]University of Maragheh, Iran, [2]University of Maragheh, Iran, [3]University of Maragheh, Iran

Using chemical materials for controlling pests has caused many side effects on organisms and environment. In this research, lethal and sublethal effects and oviposition deterrence activity of essential oils Artemisia dracunculus L. and Mentha piperita L. on the Cowpea weevil adult Callosobruchus maculatus were evaluated. Testing was performed at 26 ±1 0C, 70± 5 % RH with seven concentrations of each essential oil. Fumigant toxicity of essential oils was assessed on the adults of the pest. LC50 values for each essential oil were calculated at different time of exposure, LC50 values for A. dracunculus 24.54 µl/lair after 24h and for M. piperita were 21.21 µl/lair after 9h. Sublethal concentration (8.48 and 13.63 µl/lair respectively for essential oils of A. dracunculus and M. piperita) of essential oils negatively affected the longevity and fecundity of female adults. The sex ratio of C. maculatus offspring was not significantly affected by essential oils. Also use of the concentrations (0.02, 0.06 and 0.1 µl/g) showed great potential of these essential oils for oviposition deterrence on this pest as cause 100 and 94.5% oviposition deterrence in 0.1 µl/g For A. dracunculus and M. piperita, respectively. The results indicated high insecticide properties of both essential oils on Cowpea weevil so the use of essential oil can be recommended as a low-risk pesticide and stored pests control with high impact.

Insecticidal activity and GC/MS analysis of three essential oils on cowpea weevil *Callosobruchus maculatus* F. (Col.; Bruchidae)

Khadijeh izakmehri[1], Moosa Saber[2], Mohammad Bagher Hassanpouraghdam[3], Ali mehrvar[4]

[1]University of Maragheh, Iran, [2]University of Maragheh, Iran, [3]University of Maragheh, Iran, [4]Azrabaijan University of Tarbiat Moallem, Iran

Cowpea weevil, Callosobruchus maculatus F. (Col.; Bruchidae) is one of the most important stored product pests that make damages on seeds. Due to side effects of synthetic insecticides, more attention is devoted to the use of essential oils. Fumigant effects of the essential oil of three plants including Artemisia dracunculus L., Heracleum persicum Desf and Eucalyptus sp. were assessed on adults C. maculatus. The essential oils were extracted by Clevenger type apparatus. Essential oils were analyzed by GC and GC/MS. There were 28 chemical compounds in A. dracunculus , 21 chemical compounds in H. persicum and 47 chemical compounds in Eucalyptus sp. that are mainly among monoterpenoid groups. Acute toxicity bioassay was carried out to calculating LC50. The LC50 values were 24.5, 136.36 and 26 and µl/lit air in 24 h for A. dracunculus, H. persicum and Eucalyptus sp., respectively. The LC50 value was compared in 3 different temperature and relative humidity. The temperature affected the toxicity of the essential oils significantly but humidity did not. LT50 values for A. dracunculus , H. persicum and Eucalyptus sp. were 8.9, 10.93 and 6.3 hours, respectively. The results showed that the lethal effects of the essential oils were increased by increasing temperature and humidity. Our results showed that the essentials were effective against the pest and reduced the pest infestation. Application of these oils would be useful in IPM programs.

Lethal, sublethal and combination effects of azadirachtin and *Bacillus thuringiensis* Berliner on cotton bollworm, *Helicoverpa armigera* Hubner (Lepidoptera: Noctuidae)

Zahra Abedi[1], Moosa Saber[2], Samad Vojoudi[3], Ehsan Parsaeyan[4]

[1]University of Maragheh, Iran, [2]University of Maragheh, Iran, [3]University of Maragheh, Iran, [4]University of Maragheh, Iran

The Cotton bollworm, Helicoverpa armigera Hubner is a polyphagous and cosmopolitan pest that causes damages on various plants. The continuous use of insecticides has caused resistance and made environmental pollution. In this study, lethal, sublethal and combination effects of azadirachtin (BioNeem®) and Bacillus thuringiensis sub sp. kurstaki (Safer®) were evaluated on third larval instar of H. armigera. Bioassay tests carried out by stomach method and the artificial diet glomeration at 26±1oC, 70±5% RH and a photoperiod of 16:8(L:D)h. The LC50 value of azadirachtin and Bt were 12.95 and 96.76 µg a.i./ml, respectively. The interaction of LC20 values of the insecticides caused 56.7% mortality on third instar larvae. The LT50 value of azadirachtin and Bt were 4.78 and 3.59 day, respectively. The results showed that sublethal concentration (LC30 values) of azadirachtin and Bt negatively affected the larval and pupal weight and additively affected larval and pupal duration of H. armigera. The longevity and fecundity of female adults was significantly affected by the insecticides. The least of adult emergence ratio and pupation ratio was observed in azadirachtin. The results indicated that both of insecticides had high potential for controlling H. armigera.

Acute and population level toxicity of azadirachtin and cypermethrin on larval ectoparasitoid *Habrobracon hebetor* Say (Hymenoptera: Braconidae)

Zahra Abedi[1], Moosa Saber[2], Ali Mehrvar[3], Gholamhossein Gharekhani[4]

[1]University of Maragheh, Iran, [2]University of Maragheh, Iran, [3]Azarbaijan University of Tarbiat Moallem, Iran, [4]University of Maragheh, Iran

Habrobracon hebetor Say is an important ectoparasitoid of various lepidopteran larvae. Lethal and sublethal effects of cypermethrin and two different formulations of azadirachtin (BioNeem® and Neem Guard®) were evaluated on H. hebetor under laboratory conditions. The adults were exposed to fresh residues of the insecticides applied on glass plates at 26±1oC, 70±5% RH and photoperiod of 16:8 (L:D) h. Based on the dose-response study, the LC50 value of cypermethrin, Neem Guard and BioNeem were 5.42 , 43.54 and 10.16 µg a.i/ml, respectively. The effect of azadirachtin and cypermethrin on larval stage was tested by dipping the larvae to field recommended concentration (FRC). Emergence rate was reduced by 97.56, 39.02 and 36.58 % at cypermethrin, Neem Guard and BioNeem, respectively. For assessment of the sublethal effects, adult wasps were exposed to an LC30 of either insecticide for 24 h and then the demographic parameters of live wasps were studied. The results showed that cypermethrin and two formulations of azadirachtin negatively affected fecundity and fertility of females adults. And also the intrinsic rate of increase (rm), finite rate of increase (λ) and doubling time (DT) were significantly affected by the insecticides. The sex ratio of H. hebetor offspring was not significantly affected by the insecticides. The intrinsic rate of increase for the control, cypermethrin, Neem Guard and BioNeem exposed populations were 0.179, 0.16, 0.143 and 0.149 female offspring per female per day, respectively. The results indicated that these insecticides and H. hebetor could constitute compatible components for IPM.

Insecticidal effects of 1, 8-cineole essential oil on *Tribolium confusum* Duval (Col.: Tenebrionidae) under laboratory conditions

Jamshid Marzanghi[1], Mohammad Hasan Safaralizadeh[2], Nouraddin Shayesteh[3], Jafar Valzy[4]

[1]Urmia University, Urmia, Iran, [2]Faculty of Agriculture, Urmia University, Urmia, Iran, [3]Islamic Azad University, Mahabad Branch, Iran, [4]Tabriz Branch, Islamic Azad University, Tabriz, Iran

The uncontrolled use of synthetic insecticides is a great hazard for the environment and consumers. Essential oils were introduced as low toxic agents against mammals and non-targeted insects. The scale and duration of this disruptive activity depends on the concentration of the active agent in air and on its stability. During recent years, some plants have been receiving global attention and their secondary metabolites have been formulated as botanical pesticides for plant protection since they do not leave residues toxic to the environment, have lower toxicity to mammals and medicinal properties for humans. In order to determine their repellency and stability as repellents against Tribolium confusum du Val. (Col.: Tenebrionidae) adults, the activity of 1, 8-cineole essential oils. In this research fumigant toxicity of essential oil 1, 8-cineole was studied against 1-7 days old adults of the confused flour beetle, Tribolium confusum du Val. Bioassays were carried out at 28±1 ºC and 60 ± 5% R. H. under dark condition adopting a complete randomized block design with five concentrations of essential oil were tested in four replications with 20 adult insect in each replication. Mortality of adults was recorded at 24 h. The LC50 and LC95 value was 59.27 and 160.6 µl/L air respectively. A direct relationship between mortality rate and dose was detected. The findings of current study suggest that essential oils could also be used as insecticide against the stored product pests.

Preliminary studies on prevailing species of rose stem borer sawflies in Urmia, Iran

Nouraddin Shayesteh[1], Jamshid Akbarian[2], Shahram Aramideh[3], Mehdi Razami[4]

[1]Islamic Azad University, Mahabad Branch, Iran, [2]Faculty of Agriculture, Urmia University, Urmia, Iran, [3]Faculty of Agriculture, Urmia University, Urmia, Iran, [4]Faculty of Agriculture, Urmia University, Urmia, Iran

In a Three-year investigation during 2007-2009, efficiency of some biological and ethological characteristics of Stem Borer Sawflies' prevailing species was studied in order to diminish pest population density in Urmia rose-gardens. Genus of this economically important wasp was recognized, Syrista sp., which belongs to Cephidae family. Species of Syrista sp. has sexual dimorphism and one generation in a year. Daily average advance of larva in feeding tunnel was estimated about 5 millimeters. Yearly average infestation of rose-bushes, adult sex ratio of male/female and spatial distribution pattern were %39.33, 1: 3.71 and clumped (Negative binominal), respectively. The mortality of overwintering larvae inside infested branches by observation of ordinary autumnal pruning was %20. Treatments of larvae spring control tests were included pruning of branches´ tips, spraying pit of branches by Azinophos methyl of Iran made, spraying by Azinophos methyl of German produce in addition to control treatment. This test was conducted by completely randomized design in soft and hard branches. According to results and counting of larval mortality after 96 hours and mortality percent of treatments were 99.9 and 99.9, 75 and 25, 85 and 30, 0 and 0, respectively. Therefore infested branches tip pruning technique had the best effect between treatments in both conditions on early June and can be recommended, to be valuable either as a component of any IPM program or an independent control tool and particularly is effective due to lowering risk of environmental contamination through reducing pesticide application.

The Khinjuk psylla , Agonoscena bimaculata Mathur was reported as a pest of the Pistacia khinjuk . Life table laboratory condition (27.5 C° , 55±5 % RH and 16 L: 8 Dh) . At Pistacia vera the intrinsic rate of increase (rm) , finitrate of increase (λ) , net reproduction rate (R0) , mean generation time (T) and population doubling time (DT) were 0.12 , 1.12, 81.56 ,37.5 and 5.9 days , respectively , and at Pistacia khinjuk they were 0.11, 1.12 , 75.1 , 36.41 and 5.8 days , respectively . The resullts of this study could be seen as a starting point for further research in order to improve the management of A.bimaculata populations.

Field Evaluation of *Beauveria bassiana* and *Verticillium lecanii* against jasmin whitefly, *Aleuroclava jasmine* on citrus

Hussain Fadhil Mohammed Ali
Ministry of Science & Technology, Iraq

Pathogenicities of entemopathogenic fungi, Beauveria bassiana and Verticillium lecanii were evaluated against jasmin whitefly, Aleuroclava jasmine infested citrus trees under field conditions of three different locations. Results indicated that parasitization percentages of B. bassiana on eggs and nymph were relatively comparable to that of V. lecanii with some differences between locations. The parasitization percentages of eggs were, in general significantly lower than that of nymphs. It was found that parasitization of both fungal species tested, increased significantly with time. The results showed the probable negative effect of high temperatures and low humidity on both fungal parasitization potentials.

Efficacy of *Bacillus thuringiensis* against the larvae of *Helicoverpa armigera* and its compatibility with *Metarhizium anisopliae* and chlorantraniliprole used against this insect pest

Waqas Wakil[1], M. Usman Ghazanfar[2], Y. Jung Kwon[3], Mirza Abdul Qayyum[4], Tahira Riasat[5]

[1]University of Agriculture, Pakistan, [2]University College of Agriculture, University of Sargodha, Pakistan, [3]Kyungpook National University, Republic of Korea, [4]University of Agriculture, Pakistan, [5]University of Agriculture, Pakistan

This study was designed to evaluate Bacillus thuringiensis subsp. kurstaki and its combination with Metarhizium anisopliae and new chemistry insecticide - chlorantraniliprole against the larvae of six field population of tomato fruitworm Helicoverpa armigera Hubner (Lepidoptera: Noctuidae). The two dose rates of B. thuringiensis (0.5, 1 µg g-1), one of both M. anisopliae (1.3×106 conidia ml-1) and chlorantraniliprole (0.01 ppm) were applied alone and in combination with each other against 4th and 5th larval instars. The mortality was observed after every 24 h and the larvae were kept for pupation. The mortality was observed in Rawalpindi with lowest pupation rate by applying the combined concentrations of B. thuringiensis and chlorantraniliprole, while, the lowest mortality was observed in Gujranwala among all the tested populations. The results clearly showed that these agents may interact with other but more focused research is required to optimize the dose rates against the larval instars of tomato fruitworm.

Comparative study on the effect of *Bacillus thuringiensis* var. tenebrionis, imidacloprid and phosalone on different larval instars of *Leptinotarsa decemlineata* (Say) under laboratory conditions

Akbar Ghassemi-kahrizeh[1], Shirin Mohammadzadeh[2], Mahmoud Pooryousef Myandoab[3], Shahram Aramideh[4]

[1]Mahabad Branch, Islamic Azad University, Iran, [2]Mahabad Branch, Islamic Azad University, Iran, [3]Mahabad Branch, Islamic Azad University, Iran, [4]urmia university, Iran

In this study the susceptibility of different larval instars of Colorado potato beetle, Leptinotarsa decemlineata (Say) to Bacillus thuringiensis var. tenebrionis Ber. (as a microbial insecticide), imidacloprid (as a new insecticide) and phozalone (a widely used insecticide against this pest) was investigated in laboratory conditions. For this reason the larvae were reared on potato leaves in laboratory conditions. Then different larval instars were separated by measuring the diameter of head capsules and were used in bioassay tests. The different concentrations of commercial formulation of B.t., biobit (B.t. var. tenebrionis), confidor 200 SC (imidacloprid) and zolone EC 35% (phosalone) were tested on 1st, 2nd, 3rd and 4th instars groups of larvae. The LC50 values for these larval instars for B.t. var. tenebrionis after 144 h were 252.07, 613.21, 1731 and 3006 ppm, respectively. This criterion for imidacloprid was estimated 17.58, 41.35, 56.76 and 81.27 ppm, respectively for different larval instars in the same order after 72 h. The LC50 values for these larval instars for phosalone after 72 h were estimated 447.46, 697.88, 1020 and 1297 ppm, respectively.

Study on morphological indices of Colorado potato beetle, *Leptinotarsa decemlineata* (Say) in west Azerbaijan province

Akbar Ghassemi-kahrizeh[1], Nouraddin Shayesteh[2]

[1]*Mahabad Branch, Islamic Azad University, Iran,* [2]*Mahabad Branch, Islamic Azad University, Iran*

The Colorado potato beetle, Leptinotarsa decemlineata (Say), is a serious pest of potato, Solanum tuberosum L. worldwide. In this study, morphological indices of different biological stages of the Colorado potato beetle, Leptinotarsa decemlineata (Say) were evaluated in west Azerbaijan province. Weight, length and width of body for male and female adults, weight and length of body and head capsule diameter of different instars larvae, weight and length of pupae, egg length and number of egg in each egg mass were measured. The highest of weight, length and width average of body for adults were observed for female with mean values of 178.8±6.756 mg, 11.535±0.099 and 6.887±0.052 mm, respectively. The least and highest larval weight were observed for 1st and 4th instars with mean values of 1.300±0.082 and 88.667±6.191 mg, respectively. Average of head capsule diameter for 1st, 2nd and 3rd instars larvae were measured 0.684±0.011, 1.131±0.075 and 1.682±0.133 mm, respectively. Average number of egg in egg masses was measured 29.064±1.323.

Study on synergistic effects of henna in enhancement of pathogenicity of *Bacillus thuringiensis* Berliner on third and fourth instars larvae of Colorado potato beetle, *Leptinotarsa decemlineata* (Say)

Nouraddin Shayesteh[1], Akbar Ghassemi-kahrizeh[2]

[1]Mahabad Branch, Islamic Azad University, Iran, [2]Mahabad Branch, Islamic Azad University, Iran

The synergistic effects of henna powder in enhancement of pathogenicity of Bacillus thuringiensis var. tenebrionis, and Bacillus thuringiensis var. kurstaki on 3rd and 4th instars larvae of Colorado potato beetle, Leptinotarsa decemlineata (Say), was evaluated. Combination of 3 concentrations of henna powder (3000, 4000 and 5000 ppm) with bacteria (500 and 1000 ppm for 3rd and 4th instars larvae, respectively) was used against 3rd and 4th instars larvae in completely randomized plot design in laboratory conditions. The results revealed that there was a remarkable synergistic effect of henna powder on B.t. efficiency. The 3rd instars larval mortality for mixture of B.t. var. tenebrionis (500 ppm) with henna (5000 ppm) was 72.5% after 6 days, however the mortality of larvae treated with B.t. var. tenebrionis (500 ppm) alone was 17.5% in this time. The mixture of B.t. var. kurstaki (500 ppm) with henna (5000 ppm) had caused 85% mortality in the 3rd instars larvae during 6 days. This concentration of B.t. var. kurstaki produced 22.5% mortality on this larvae. The mortality for 4th instars larvae treated with B.t. var. tenebrionis (1000 ppm) was 12.5% after 6 days, however this rate for 4th instars larvae treated with mixture of B.t. var. tenebrionis (1000 ppm) and henna (5000 ppm) was 47.5% in this time. The mortality of 4th instars larvae treated with mixture of B.t. var. kurstaki (1000 ppm) with henna (5000 ppm) was 3.4 times as much of the mortality of fourth instars larvae treated with B.t. var. kurstaki (1000 ppm).

Genetic rice breeding for resistance to the *Oryzophagus oryzae* in Brazil

Jose Francisco da Silva Martins[1], Paulo Ricardo Reis Fagundes[2], Orlando Peixoto de Morais[3]

[1]Brazilian Agricultural Research Corporation, Brazil, [2]Brazilian Agricultural Research Corporation, Brazil, [3]Brazilian Agricultural Research Corporation, Brazil

The Brazilian rice water weevil (RWW) Oryzophagus oryzae (Col.: Curculionidae) is the major insect pest in flooded rice in South of Brazil. Adults feed on rice leaves. However, is the larval root pruning that promotes the main yield losses. Cultivars resistant to RWW is considered a promising alternative to reduce the insect damage to the flooded rice and consequently the insecticide use, operational costs and risks of environmental contamination. The rice resistance to the RWW belongs to the antixenosis, antibiosis and tolerance types. The antixenosis and antibiosis would reduce the insect oviposition level and cause the larval death in the growth initial phase, respectively. The tolerance is characterized by root system recovery after the larval pruning. Studies started in 1980 have indicated a possibility to obtain rice resistance to RWW based on antixenosis, antibiosis and tolerance mechanisms. Initially commercial varieties, advanced breeding lines, land races, alien resistance sources are evaluated in rice field conditions, under natural insect infestation. Selected genotypes of the preliminary evaluation are revalued under field and greenhouse conditions, in cages, with high insect infestation and with and without host plant choice. The cultivars Dawn and BRS Atalanta were selected as antixenosis and antibiosis resistant sources while BR-IRGA 413 as tolerant resistant source. These cultivars are being used as a source of genes in a population of recurrent selection in rice breeding program of Embrapa. In this context, the objective is to present the state of research on genetic resistance of rice to the RWW in Brazil.

A effective pesticide? Spirotetramat for the control of the *Cacopsylla chinensis* Yang & Li (Hemiptera: Psyllidae)

Ya-Jun Gong[1], Shu-Jun Wei[2], Bao-Cai Shi[3]

[1]*Beijing Academy of Agriculture and Forestry Sciences, China,* [2]*Beijing Academy of Agriculture & Forestry Scinece, China,* [3]*Beijing Academy of Agriculture and Forestry Sciences, China*

The spirotetramat is a new two-way systemic and absorptive insecticide and miticide developed by Bayer company, belong to Tetronic acid. Here, the field control efficacy of the spirotetramat to the Cacopsylla chinensis was studied. The result show that spirotetramat has a good control efficacy long after the pray. The control effects of 2000, 3000 and 4000 concentrations are above 89% after 28 d, and among 81-89% after 91 d, obviously higher than the control pesticides of fenpropathrin, deltamethrin, imidacloprid and emamectin-benzoate. Our research indicate that the spirotetramat could successfully control the Cacopsylla chinensis in the whole year with one time spray.

Mechanism of resistance in wild relatives of pigeonpea against *Maruca vitrata* Geyer (Lepidoptera:Pyralidae)

Chitra NArayanasamy[1], Palanisamy Soundararajan[2], Sheshadri Geetha[3]

[1]National Pulses Research Centre, Tamil Nadu Agricultural University, India, [2]National Pulses Research Centre, Tamil Nadu Agricultural University, India, [3]National Pulses Research Centre, Tamil Nadu Agricultural University, India

Maruca vitrata Geyer (Lepidoptera: Pyralidae) is one of the most destructive insect pest of pigeonpea owing to the feeding habit on the reproductive structures of the crop. The levels of resistance are considerably low in the cultivated germplasm and development of resistant varieties with incorporation resistant genes from wild relatives can be an important component in insect pest management. Hence, the ovipositional and feeding preference of adults and larvae on the pigeonpea wild relatives viz., Cajanus scarabaeoides and Rhyncosia rufescens were evaluated in comparison with the cultivated variety VBN (Rg) 3 under field and laboratory conditions. Under field conditions, there was no oviposition on C.scarabaeoides and R. rufescens consequently no damage under field conditions as against 12 egg/10 cm twig/plant and 20 floral webs/plant with one larvae/web in VBN (Rg)3. Under laboratory conditions, both under no choice and free choice test, there was no oviposition on the wild relatives as against 8eggs/twig in VBN (Rg) 3. The feeding damage of the third instar larvae on the flowers were highest on VBN (Rg) 3 (80.00%), followed by R.rufscens (40.00%) and C.scarabaeoides (37.78%) while on the pods the larvae failed to feed on the wild relatives as against 47 per cent damage on VBN (Rg) 3. The results clearly indicate the ovipositional and feeding non preference in the wild relatives.

Seasonal migratory behaviors of *Mythimna separata* (Lepidoptera:Noctuidae) in Northeast China

Yunhui Zhang[1], Zhi Zhang[2], dengfa cheng[3]

[1]Chinese Academy of Agricultural Sciences, China, [2]Chinese Academy of Agricultural Sciences, China, [3]Chinese Academy of Agricultural Sciences, China

Seasonal migratory behaviors of Mythimna separata (Walker) in Northeast China were studied by long-term observation using a vertical-looking radar (VLR) and light trapping in Jilin province, in combination with analysis of large-scale wind systems and trajectory simulation based on GIS. Results showed that migration of M. separata only occurred on a few nights during each of three distinct migration periods, that it flew at obviously different altitudes depending on season and time of night, and that its migratory behavior was significantly influenced by meteorological conditions, especially the large-scale atmospheric circulation. The long-distance migrations were wind-assisted, and most of the individuals were able to continue in flight throughout the night. The migration altitude in spring was mainly 300-600 m, while in autumn it was relatively low, mainly below 500 m. Radar echoes in summer showed obvious stratification, indicating that the migrants were sometimes concentrated into two or more layers with a maximum height of up to 1000 m. Trajectory analysis showed that in spring, populations of M. separata flying over the radar station originated from the southwest, probably from Shandong Province in mid-July, however, populations were locally produced and dispersed relatively short distances under the influence of convective weather. In autumn, populations of M. separata originating from the Hulun Buir region of Inner Mongolia were observed to fly on northwesterly winds to the southeast of Jilin province.

Insecticidal potentiality of *Datura innoxia* leaf extracts against the adult cluster bug *Agonoscelis pubescens* (Thunberg) (Heteroptera: Pentatomidae)

Hashim Ahmed Elmassad[1], Abdalla Abdelrahim Satti[2], Zuhair Alfadel Alabjar[3]

[1]Sudan Academy of Science, Sudan, [2]Sudan Academy of Science, Sudan, [3]Sudan Academy of Science, Sudan

The cluster bug (Agonoscelis pubescens) is a major pest of Sorghum bicolor and some other crops in Sudan. Despite the high cost of its chemical control, the population of the pest that attacks the crop retains more or less similar trend every year. Such demerits of synthetic insecticides have advocated the search for effective ecologically sound alternatives. Therefore, laboratory experiments were carried out to evaluate the insecticidal potentiality of Datura innoxia leaf extracts against the adult A. pubescens, as compared with a standard insecticide. The leaves were extracted with water and two organic solvents (hexane and ethanol). The parameters included; comparisons of three application techniques (spraying, dipping and filter paper methods) and bioassays of the different extracts. In both cases, mortality means were recorded at different intervals (2, 3, 5 and 7days) from treatments. The results revealed that the spraying of A. pubescens bugs on plant leaves gave the best effect than the other tested techniques. Regarding bioassays, leaf hexane extract exerted significantly the highest mortality levels as compared with the other extracts, though was surpassed by the insecticide. In all extracts, the mortality rates generally increases with increasing concentration and exposure time. Moreover, Datura extracts also seem to manifest a hormonal effect on the insect as deformed hind legs were appeared in some treatments. In conclusion, the study proved that leaves of D. innoxia contain variable biological activities on the pest, and invites more research to isolate and characterize their active compounds for proper utilization as natural biocides.

Evaluation of synthetic (Indoxacarb, Flubendamide, Spinetoram, Flafenoxuaron, Chlorfenypyr, Leufenuron and Coragen) and Microbial pesticides (Emamactin and Spinosad) against *Spodoptera litura*

Fawad Zafar Ahmad Khan[1], Noor Abid Saeed[2], Abdul Khaliq[3], Muhammad Sagheer[4], Sajid Nadeem[5]

[1]University of Agriculture, Faisalabad, Pakistan, Pakistan, [2]Nuclear Institute of Agriculture and Biology, Faisalabad, Pakistan, [3]University of Agriculture, Faisalabad, Pakistan, [4]University of Agriculture, Faisalabad, Pakistan, Pakistan, [5]Nuclear Institute of Agriculture and Biology, Faisalabad, Pakistan

Experiments were conducted to evaluate the effect of synthetic and microbial insecticides against the larval stage of Spodoptera litura. The experiments were performed in the Plant Protection Division, Nuclear Institute for Agriculture and Biology, Faisalabad, Pakistan. Uniform population of laboratory culture (F3 Generation) of S. litura was used. Twenty 3rd instar larvae were released in each treatment. Filter paper method was used. Different concentrations of synthetic insecticides, Indoxacarb (1.25, 5.25. 10 and 20ppm), Flubendamide (3.15,6.25,12.5, 25 and 50 ppm), Spinetoram (12, 24, 48,96 and 192 ppm), Flafenoxuaron (6.25, 12.5, 25, 50, 100 ppm), Chlorfenypyr (20.6. 41.5, 82.5, 165 and 330 ppm) Leufenuron (6.25, 12.5, 25 and 50ppm), Coragen (10,20,40,80, 160ppm) and that of the microbial insecticides; Emamectin (2.375, 4.75, 9.5, 19.5 and 38 ppm) and Spinosad (12, 24, 48, 96 and 192), were used to determine the larval mortality. It was found that at lowest concentrations, Leufenuron proved to more effective causing 33% of larval mortality while at highest concentrations of Indoxacarb (20 ppm) and Chlorfenpyr (100 ppm), 100% mortality was observed. The result showed that synthetic insecticides have high acute action as compared to the microbial insecticides.

The synergitic effect of Henna powder on increasing efficacy of *Bacillus thuringiensis* var. Kurstaki against third larval instar of Pistachio white leaf moth *Ocneria terebinthina* (Lep.: Lymanteridae)

Zahra Sheibani Tezerji

Islamic azad university, Rafsanjan branch, Iran

In this research the susceptibility of the third larval instar of Ocneria terebinthina (Lep.: Lymanteridae) to Bacillus thuringiensis var. kurstaki alone and in the mixing with henna powder (Lawsonia alba (Litraceae)) was investigated. The eggs of the insect were collected from orchards where located around Anar in Rafsanjan. The third larval instar was separated by measuring the head capsule width, and then used in all bioassays. In bioassay, LC50 value of Bt in third larval instar was determined by using treated pistachio offshoot. The data was analyzed by log-probit transformation using the MSTATC software. LC50 value for third larval instar was estimated 2817.34 ppm. Then the synergitic effect of henna powder on efficacy of Bt was evaluated. Several doses of henna powder were combinated to the minimum lethal dose of Bt for third larval instar (more resistant than first and second larval instars) in complete randomized block design in three replicates. The results revealed henna powder has synergitic effect on Bt. So that, mixture of Bt (1000 ppm) and henna powder (6000 ppm) caused 81.11% mortality whereas Bt only caused 17.77 mortality. According to the collected data in this research and the selective nature of Bt it can be concluded that this microbial compound in combination with henna powder synergist can control of Ocneria terebinthina reasonably.

Reproductive toxicity of imidacloprid and bifenthrin to the biological control agent, *Chrysoperla carnea*

Hafiza Tahira Gul[1], Shafqat Saeed[2], Attaullah Khan Pathan[3]

[1]University College of Agriculture, BZU, Multan, Pakistan, [2]University College of Agriculture, BZU, Multan, Pakistan, [3]PARC Research Station, BZU, Multan, Pakistan

Lethal effect of two insecticides; Imidacloprid and Bifenthrin, was checked on survival and reproduction of Chrysoperla carnea adults. C.carnea adults were collected from field and reared in the IPM Station, BZU, Multan. Experiments were completed on F1 generation of the test organism. The adults were provided fresh water and artificial diet. Bifenthrin 10EC and Imidacloprid 20SL were used for experiment. Four replicates of each concentration with three pairs of adults were used. Different concentrations of Imidacloprid (500, 250, 166.6, 125 and 100ppm) and Bifenthrin (500, 250, 125, 83.3, 62.5 and 50ppm) were applied so as to evaluate the possible effect of both of these insecticides on the biology of C. carnea. Treated water was fed to the adults for four consecutive days. After feeding, the biology of insect was observed. The results showed that in the case of Imidacloprid, mortality was at its maximum on the field dose, i.e. 500 ppm, whereas the hatching percentage was also significantly reduced at the same dose rate. In the case of Bifenthrin, highest mortality was recorded at 500 ppm and there is a significant decrease in egg laying and percentage hatching. Imidacloprid proved to be more toxic as compared to the other insecticide tested. Hence, it can be concluded that the synthetic insecticides has a definite impact on the biology of biological control agents, as in the case of C.carnea.

Analysis of physio-morphic traits in different host plants associated with resistance to *Phenacoccus solenopsis*: An invasive pest in Pakistan

Muhammad Rafiq Shahid[1], Muhammad Jalal Arif[2], Muhammad Dildar Gogi[3]

[1]cotton Research Institute, AARI, Faisalabad, Pakistan, [2]University of Agriculture, Faisalabad, Pakistan, [3]University of Agriculture, Faisalabad, Pakistan

Phenacoccus solenopsis Tinsley(Pseudococcidae:Hemiptera) is sucking insect pest and polyphagous in nature. Twenty five different host plants were screened against P. solenopsis and their physicomorphic traits were determined to correlate their role against pest population. Among tested plant species, most favorable host plants of mealy bug on the basis of population were Gossypium hirsutum (69.74±10.5), Solamum melongena (62.41±10.0), Helianthus annuus (61.83±10.0), Hibiscus rosa-sinensis) (61.1±10.0) and Lantana camara (55.83±9.75) but the least preferred plants were tandla Digera arvensis (1.57±1.00) and Conyza bonariensis (3.83±1.75). Significant variations were observed in all the morphological plant characters recorded from different plant species. The maximum leaf thickness per plant was 2.04±0.23µm in plant species S. melongena while minimum thickness of leaf was recorded from lehli (0.25±0.02µm). Maximum trichome density per plant was 444±72.4 of sunflower followed by 411.6±19.6, 399±52, 391.6±22.0, in C. bonariensis, Abelmoschus esculentus and Withania somnifera respectively but minimum 2.33±1.45 of Chinopodium morale, followed by 2.66±1.4, 3±2.08 of , Portulaca oleracea and Trianthema portulacastrum) respectively. The maximum hair length per plant 2.62±0.07 mm was of sunflower followed by 2.55±0.03 mm in Okra, 2.53±0.06 mm in both S. melongena and G. hirsutum. It was concluded that plant characters including trichome density and hair length favor mealy bug population showing r-values of 0.357*, 0.190 respectively, but leaf size, leaf width (leaf area) and leaf thickness exerted negative effect on pest population showing r-values of -0.172, -0.285 respectively.

Investigation on the most appropriate pattern, sample unit and sample universe to estimate *Tetranychus urticae* Koch. population in common bean, *Phaseolus vulgaris* fields.

Nasim Abolfathi

Shahid Chamran University, Ahvaz, Iran

Abstract: Two spotted spider mite, Tetranychus urticae Koch. is one of the most important pests of common bean in most areas of Iran, including the Lorestan province. The most appropriate pattern, unit and universe sampling of mite population were investigated in common bean fields in Borujerd, Dorud and Azna in 2008. In this study, two patterns of movement in the field (X shape and zigzag) were used. Statistical analysis showed that, there was no significant difference between these two patterns, in related to CV, RV and RNP parameters. The results showed that, sampling should be done from top, middle and bottom of plant height. In addition, comparison of three sample units, 1.5 leaves per plants (a half leaf from each plant height), 3 leaves per plants (a leaf from each plant height) and 6 leaves per plants (two leaves from each plant height) showed that there is no significant difference between CV and RV amounts of each female, nymph and egg populations with related to CV, RV and RNP parameters. But sample unit 1.5 leaves with the highest amount of RNP, showed significant difference comparison to two sample units 3 and 6 leaves. Based on this research, sample unit with 1.5 leaves (three half leaves, left and right consecutively from three plant height) is recommended in sampling of T.urticae populations in common bean fields.

ABCC2 functions as a receptor for *Bacillus thuringiensis* Cry toxin.

Shiho Tanaka[1], Kazuhisa Miyamoto[2], Hiroaki Noda[3], Ryoichi Sato[4]

[1]Tokyo University of Agricultuer and Technology, Japan, [2]Institute of Insect and Animal Sciences, Japan, [3]National Institute of Agrobiological Sciences, Japan, [4]Tokyo University of Agricultuer and Technology, Japan

Transgenic Crops which produces Bacillus thuringiensis Cry toxins (Bt-Crop) has been used widely because of its advantages as a safe and environmentally friendly product. However, with the expansion of planting the Bt-Crop, evolution of Bt-Crop resistant strains in the field population has become clear. Recently, ABC transporter subfamily C2 (ABCC2) which had never been thought as a molecule associated with the mode of action of Cry toxins was reported as a causal factor of Cry1A toxin's resistant insects. Here, we report evidences that Bombyx mori ABCC2 (BmABCC2) functions as the most important receptor in this insect for Cry toxins and mutations occurred in the toxin-binding regions and ATP binding cassette in this molecule could cause generation of resistant strains. When BmABCC2 alone or both BmABCC2 and cadherin-like receptor, BtR175 was ectopically expressed in Spodptera frugiperda Sf9 cells, the cells became susceptible to Cry1Aa, Cry1Ab, Cry1Ac, Cry1Fa and even Cry8Ca, but not to Cry3Bb. On the contrary, BtR175 could not offer susceptibility to the cells. From these, susceptibility of cells which expressed both BmABCC2 and BtR175 seemed correlated well to susceptibility of B. mori larvae. Alanine-replacement mutations made in the extra-cellular loop 3 and 5 regions of BmABCC2 removed the susceptibility-giving function from BmABCC2, suggesting that these are toxin binding regions. Mutations introduced in Walker A and Signature motif region which are critical to ATPase activity of ABCC2 also removed the susceptibility-giving function from BmABCC2. Now, we are trying to clarify the real meaning of these phenomena.

Characterization of cell line developed from the neonate larvae of *Papilio demoleus* Linnaeus (Lepidoptera: Papilionidae)

Weifeng Ding[1], Ying Feng[2], Xin Zhang[3], Xiao-Ming Chen[4], Xian Li[5], Cheng-Ye Wang[6], Tao Ma[7]

[1]Research Institute of Resources Insects of the Chinese Academy of Forestry, China, [2]Research Institute of Resources Insects of the Chinese Academy of Forestry, China, [3]Research Institute of Resources Insects of the Chinese Academy of Forestry, China, [4]Research Institute of Resources Insects of the Chinese Academy of Forestry, China, [5]Research Institute of Resources Insects of the Chinese Academy of Forestry, China, [6]Research Institute of Resources Insects of the Chinese Academy of Forestry, China, [7]Research Institute of Resources Insects of the Chinese Academy of Forestry, China

A new cell lines RIRI-PaDe-3 developed from the neonate larvae of Papilio demoleus Linnaeus was established in the modified Grace medium supplemented with 20% fetal bovine serum (FBS) and incubated at 28 ºC. The cell line consisted of short spindle and round cells, both of them were wall-adhering cells. The chromosome numbers of cells varied widely from 28 to 136. The population-doubling time (PDT) of cells was 47.6 h at 71th passage. Comparison of nuclear ribosomal ITS sequences found in the cell line with those found in neonate larvae confirmed that the cell line was of P. demoleus Linnaeus origin. This cell line was susceptible to the Apocheima cinerarius nucleopolyhedrovirus (AciNPV) and Autographa californica nucleopolyhedrovirus (AcNPV). We conclude that the RIRI-PaDe-3 cell line will be a useful tool for studying virus replication.

Economized media for spore production of white mascardine, *Beauveria bassiana* (Balsmo) Vuillemin and its pathogenicity on *Brontispa longissima*

Paweena Buchatian[1], Wiwat Suasaard[2], Anuchit Chinajariyawong[3]

[1]National Biological Control Research Center (NBCRC), Thailand, [2]Kasetsart University Kamphaeng Saen Campus, Nakhon Pathom, Thailand, [3]National Biological Control Research Center (NBCRC), Thailand

Mass-production of entomopathogenic microorganisms is a prerequisite for their use in microbial control of pest insect programs. Four different types of media, corn, sorghum, the Sao Hai rice variety and the broken unpolished rice pieces, were laboratory evaluated for economized spore production of the entomopathogenic white mascardine, Beauveria bassina in four incubation periods, 7, 14, 21 and 28 days. There was a positive trend of spore produced, 2.14 x 109, 3.06 x 109, 3.86 x 109 and 4.13 x 109 spores/ml when cultured on broken unpolished rice pieces medium, increased significantly over other tedt media. As a result, the broken unpolished rice pieces medium was the most suitable one for the spore production among the test media. Subsequent test of pathogenicity of the fungi (density 1x 108 spores/ml) with different ages of spores, 7, 14, 21 and 28 days old, on adults of Brontispa longissima Gestro (Coleoptera: Hispidae), an economic insect pest of coconut, exhibited a quadratic equation, % mortality of B longissima = 7.9429+8.7592(day)-0.2332(day)2, [R2 = 0.8134 (P<0.01)]. It caused 90% mortality of the adult of B longissima when its spores 18.78 days old under control environment (25+2 0C, 75+5%RH, 24 hr light).

Analysis of two molecules determining susceptibility to Cry1 toxin in *Ostrinia scapulalis*

Haruka Endo[1], Ryoichi Sato[2]

[1]Graduate School of Bio-Applications & Systems Engineering, Tokyo Univ. of Agriculture & Technology, Japan, [2]Tokyo Univ. of Agriculture & Technology, Japan

Cry toxins are crystalline insecticidal proteins produced by Bacillus thuringiensis. Each of them has unique specificity of target insects. This specificity is largely determined by the specific interaction between Cry toxins and their receptors located at the surface of midgut epithelial cells. The lepidopteran insect, Ostrinia scapulalis, is natural resistant to Cry1Aa. We hypothesized that its receptor does not interact with Cry1Aa, and so binding affinity between Cry1Aa and cadherin-like protein which has been regarded as an essential receptor for Cry1As in lepidopteran insects was analyzed. As a result, cadherin-like protein derived from O. scapulalis bound Cry1Aa with high affinity corresponding to that of susceptible insects, suggesting that cadherin-like protein is functional but its function alone cannot induce somatic death. Then we focused on ABC transporter subfamily C2 (ABCC2), a new candidate receptor for cry toxins found as the responsible gene for resistance. According to our recent result, Sf9 cell ectopically expressing Bombyx mori ABCC2 was 10-1000-fold highly susceptive to Cry1As than cadherin-like protein-expressing cell. Therefore, we hypothesized that ABCC2 may be a significant receptor in determining O. scapulalis larvaes' susceptibility to Cry1Aa. Cadherin-like protein or ABCC2 from O.scapulalis ectopically expressed in Sf9 cell and cell susceptibility is now being assessed. We will report this result and discuss the molecule conferring susceptibility or natural resistance to individual insect against Cry toxins.

The baculovirus uses a stolen host phosphatase to induce enhanced locomotory activity in host caterpillars

Susumu Katsuma[1], Yasue Koyano[2], WonKyung Kang[3], Ryuhei Kokusho[4], Shizuo George Kamita[5], Toru Shimada[6]

[1]The University of Tokyo, Japan, [2]The University of Tokyo, Japan, [3]RIKEN, Japan, [4]The University of Tokyo, Japan, [5]University of California, U.S.A., [6]The University of Tokyo, Japan

Pathogens are known to usurp or alter the behavior of their hosts for their own benefit. Such behavior modification by animal and even plant viruses is widely observed in insect hosts. One of the earliest documented examples of such behavior modification is Wipfelkrankheit or tree-top disease of caterpillars. A hallmark of this disease is enhanced locomotory activity (ELA) that causes the diseased caterpillars to migrate to the upper foliage of the host plant where they die. We now know that the causative agent of Wipfelkrankheit is a large, double-stranded DNA virus in the family Baculoviridae. Baculoviruses form a large group of arthropod-specific pathogens that commonly attack lepidopteran insects. Two baculovirus genes, protein tyrosine phosphatase (ptp) and ecdysteroid UDP-glucosyltransferase (egt), have been shown to be involved in the induction of ELA such as climbing behavior in baculovirus-infected caterpillars. Here we dissect the functional role that baculovirus PTP plays in the induction of ELA. We surprisingly found that PTP functions as a virus-associated structural protein and not as an enzyme in regard to the induction of ELA. We show that PTP plays a crucial role in virus infection of brain tissues, and hypothesize that this infection results in pathogen control of insect behavior. Since ptp was likely captured from an ancestral host by horizontal gene transfer, our findings tell an amazing story of how the modern baculovirus uses a captured host gene in a completely different way from how it was likely used in the ancestral host.

Comparative proteomic analysis reveals the mechaminsm of morphological and physiological changes of *Bacillus thuringiensis* YBT-1520 under heat stress and its survival strategies

Mingshun Li[1], Dandan Wu[2]

[1]*Huazhong Agricultural University, China,* [2]*Huazhong Agricultural University, China*

Bacillus thuringiensis (Bt) has been widely used for 50 years as a safe biopesticide for controlling agricultural and sanitary insect pests because of its insecticidal crystal proteins. In this study a proteomic approach conbined with physiological investigation was used to describe the proteomic and physiological changes to reveal the survival strategies of Bt YBT-1520 under a long-term heat stress condition (42°C). The changes of the intracellular proteome under heat stress were as follows: (i) some of the heat shock proteins of class I and II were still induced under long-term heat stress; (ii) three non-classical heat shock proteins were also induced under long-term heat stress (iii) 83% of the differentially expressed intracellular proteins decreased (iv) about 50% of the decreased proteins were recovered at the late stage of heat stress condition . Heat stress mainly influenced the characteristics of YBT-1520 on four aspects: (i) the ability of synthesis of ICPs and other potential pathogenic factors were lost or significantly decreased; (ii) cell adhesion and motility were also lost; (iii) the cells did not sporulate, (iv) cells kept accumulating PHB. Proteomic analyses to the physiological changes revealed some strategies of YBT-1520. The ?rst strategy is to up-regulate and down-regulate metabolic enzymes. The second strategy is to increase the synthesis and accumulation of PHB. Under heat stress condition, these strategies would help cells to gain more tolerance to heat stress.

Gaucher disease is caused by defective human glucocerebrosidase. This disease can be classified according to the symptomatic states in 3 types. One has the acute neurodegenetion. However, the molecular mechanism of Gaucher disease is totally unknown. To address the molecular mechanism, we generated Drosophila lines overexpressing human normal and mutated glucocerebrosidase gene (R120W, L444P+A456P+V460V) in the eyes using GMR-GAL4 driver. Three lines of mutated transgenic flies showed defective morphology in Drosophila eyes. Here, we present the data showing a new molecular mechanism of Gaucher disease by using Drosophila model. Furthermore, I talk about the way to prevent the neurodegeneration of Gaucher disease.

Role of the polyhedrin promoter in enhanced locomotory activity induced by baculovirus

Ryuhei Kokusho[1], Toru Shimada[2], Susumu Katsuma[3]

[1]The University of Tokyo, Japan, [2]The University of Tokyo, Japan, [3]The University of Tokyo, Japan

The baculovirus is a classic parasite that alters the behavior or physiology of its host so that progeny transmission is maximized. Baculoviruses do this by inducing enhanced locomotory activity (ELA) that causes the host caterpillars to climb to the upper plant foliage. Recent studies have reported that two baculovirus genes, protein tyrosine phosphatase (ptp) and ecdysteroid UDP-glucosyltransferase (egt), are involved in the induction of this behavior. We have performed locomotion screening assays to find new ELA-associated genes, using Bombyx mori nucleopolyhedrovirus (BmNPV) and its host insect, B. mori. Here we report a novel ELA-associated gene, polyhedrin (polh), which is the most famous baculovirus gene encoding a major structural protein of viral occlusion body. Surprisingly, a polh promoter-defective mutant (polh-proD) did not induce ELA, although neither Polh protein nor polh mRNA is essential for ELA induction. This indicates that the polh promoter region itself is crucial for ELA induction. To assess why polh-proD cannot induce ELA, we next examined the viral propagation in both cultured BmN cells and B. mori larvae. In BmN cells, polh-proD produced budded viruses (BVs) comparable to WT virus, whereas BV titers in the hemolymph of polh-proD-infected larvae were significantly lower than those of WT-infected larvae. In addition, viral gene expression in polh-proD-infected brain remained at a low level even at a late stage of the infection. These results suggest that the polh promoter has a key role in ELA and viral propagation in brain is an important process for ELA induction by baculovirus.

Host range of new *Bacillus thuringiensis* pest biocontrol agents from Kyrgyzstan

Tinatin Doolotkeldieva
Kyrgyz-Turkish Manas University, Kyrgyzstan

Naturally occurring entomopathogens are important regulatory factors in insect populations. The most widely used and the most promising microbial control agent is the bacterium Bacillus thuringiensis. To isolate unknown and known BT serovars , the dead and diseased insects and soil samples were collected mainly in pristine habitats of Kyrgyzstan. Isolated natural strains of Bacillus thuringiensis were analyzed by specific primers for Cry I (Lep IF, Lep IR), Cry 3 (CoII F, CoII R) and Cry 4 (Dip IF, Dip IR) crystal endotoxin genes. The results have revealed that a natural isolate 55 S from soil was identified as Bacillus thuringiensis serovar chinensis with two - Cry 3 and Cry I genes, a strain 12-06 isolated from dead leaf beetle was identified as Bacillus thuringiensis serovar pakistani with Cry I-gene, whereas a strain 24.3, isolated from soil was identified as Bacillus thuringiensis IBL 200 with Cry 4 ? genes. We evaluated the efficiency and the host range of isolated B. thuringiensis strains on the larvae stage of pests from Lepidoptera, Hymenoptera and Coleoptera orders. Liquid formulations were compared in laboratory bioassays; larvae were feed on treated plant leaves and followed by efficiency in open field experiments. LC50 and LC95 values for the Bt strains and their formulations show high susceptibility of Helieoverpa armigera Hbn, Lymantria dispar L, Archips rosana L, Leptinotarsa decemlineata S, Leucoma salicis L.,Coliroa cerasi L. The range of host specialization of new natural Bacillus thuringiensis isolates was broad.

Cooperation between two receptors for phagocytosis in defense against bacterial infection in *Drosophila melanogaster*

Akiko Shiratsuchi[1], Yoshinobu Nakanishi[2]

[1]*Kanazawa University, Japan,* [2]*Kanazawa University, Japan*

Phagocytosis sits at the front line in innate immunity to fight against infection with pathogenic bacteria. In Drosophila, a type of blood cells called plasmatocytes is responsible for the phagocytic elimination of invading bacteria. Plasmatocytes possess two membrane-proteins, Draper and integrin-betanu, and we here examined the possibility that these receptors are involved in the phagocytosis of bacteria. Biochemical and genetic experiments revealed that Draper and integrin-betanu are both required for a maximal level of the phagocytosis of Staphylococcus aureus. A loss of both receptors had severer effects than a loss of either receptor alone on phagocytosis, bacterial growth in flies, and fly death upon infection. A genetic analysis of a role of cell wall components in the susceptibility of S. aureus to phagocytosis showed the importance of lipoteichoic acid and peptidoglycan. Finally, Draper and integrin-betanu bound to lipoteichoic acid and peptidoglycan, respectively. These results indicated that the Draper- and integrin-betanu-mediated phagocytosis of S. aureus take place independently through differential association between phagocytosis receptors and cell wall components. Taken together, Drosophila plasmatocytes are likely to use two receptors for effectively eliminating invading bacteria to survive infectious diseases.

Ribosomal RNA degradation during abortive nucleopolyhedrovirus infection of BM-N cells derived from the silkworm, *Bombyx mori*

Rina Hamajima[1], Yuya Ito[2], Michihiro Kobayashi[3], Motoko Ikeda[4]

[1]Nagoya University, Japan, [2]Nagoya University, Japan, [3]Nagoya University, Japan, [4]Nagoya University, Japan

Nucleopolyhedroviruses (NPVs) generally display a high degree of host specificity. Certain NPV-infected insect cells induce anti-viral responses such as apoptosis or global protein synthesis shutdown, resulting in abortive infection. BM-N cells derived from the silkworm, Bombyx mori, are permissive for homologous B. mori NPV (BmNPV), while non-permissive for heterologous NPVs, including Autographa californica multiple NPV (AcMNPV), Hyphantria cunea MNPV (HycuMNPV), Spodoptera exigua MNPV (SeMNPV), and Spodoptera litura MNPV (SpltMNPV). In this study, we demonstrated that severe ribosomal RNA (rRNA) degradation occurred in BM-N cells upon infection with AcMNPV, HycuMNPV, SeMNPV, and SpltMNPV, while no detectable rRNA degradation was observed in BmNPV-infected BM-N cells. rRNA degradation observed in BM-N cells commenced by 4 h pi. Using five lepidopteran cell lines, S. frugiperda Sf9, S. exigua Se301, Sphilosoma imparilis Splm, Lymantria dispar Ld652Y, and B. mori BM-N, and a dipteran cell line Drosophila melanogaster S2, we found that only the BM-N cells exhibited rRNA degradation upon infection with AcMNPV and HycuMNPV. To determine a possible viral protein(s) that was responsible for rRNA degradation in HycuMNPV-infected BM-N cells, we conducted transient expression assays with a cosmid library covering entire HycuMNPV genome and identified HycuMNPV P143 (Hycu-P143) as a viral protein that was responsible for the rRNA degradation. Analyses with plasmids expressing P143 from AcMNPV (Ac-P143), Se-P143, or Splt-P143, showed that these P143 proteins also induced rRNA degradation in BM-N cells. In addition we found that BM-N cells transfected with plasmids expressing Ac-P143, Hycu-P143, Se-P143, and Splt-P143 underwent severe apoptosis.

Pathological characteristics of *Lymantria dispar* Nucleopolyhedroviruses Isolated from diseased larvae collected In Japan

Tomoya Sano[1], Ayako Hirao[2], Madoka Nakai[3], Yasuhisa Kunimi[4]

[1]Tokyo University of Agriculture & Technology, Japan, [2]Tokyo University of Agriculture & Technology, Japan, [3]Tokyo University of Agriculture & Technology, Japan, [4]Tokyo University of Agriculture & Technology, Japan

The gypsy moth, Lymantria dispar is one of the most important pests of a Japanese larch in Japan. Mitochondrial DNA sequences show that L. dipar is divided into three strains: European strain, Asian strain, and Hokkaido strain. The latter two strains distribute in Japan. L. dipar periodically outbreaks and nucleopolyhedrovirus (NPV) and Entomophaga maimaiga play a role in the downfall of L. dispar populations at the end of outbreaks in Japan. L. dispar NPV (LdNPV) was isolated from diseased larvae collected in Hokkaido (LdNPV-Ho) and in Iwate Prefecture (LdNPV-Iw) in Japan. Those two isolates were evaluated against Gypchek (LdNPV-Am) which is a viral insecticide registered in USA for the gypsy moth control. Restriction endonuclease analysis showed that LdNPV-Ho, LdNPV-Iw and LdNPV-Am were genetically different each other. Droplet feeding bioassays with second instar larvae of the Asian strain and the Hokkaido strain showed that there were no differences in virulence and yield of occlusion bodies among three isolates. Killing time of larvae of the Hokkaido strain infected with LdNPV-Am was significantly longer than that larvae infected with either LdNPV-Ho or LdNPV-Iw. Those results suggested that all three isolates appeared suitable for the control of the Asian and the Hokkaido strains of the gypsy moth.

Molecular responses of non-permissive cell lines to inoculation with *Adoxophyes* nucleopolyhedroviruses (Baculoviridae)

Yasumasa Saito[1], Yasuhisa Kunimi[2], Madoka Nakai[3]

[1]Tokyo University of Agriculture and Technology, Japan, [2]Tokyo University of Agriculture and Technology, Japan, [3]Tokyo University of Agriculture and Technology, Japan

Baculoviruses often fail to replicate in insect cell lines, even when the cell line was established from the natural host of the virus. In this study, we monitored the molecular responses to three baculoviruses in non-permissive cell lines, and compared them to that in a permissive cell line. A nucleopolyhedrovirus isolated from Adoxophyes honmai larvae (AdhoNPV) was not infectious to the AhL-83 cell line derived from A. honmai (Tortricidae). Another narrow-host-range virus, A. orana NPV (AdorNPV), was also administered to AhL-83 cells, and both AdhoNPV and AdorNPV were further administered to cell lines derived from Homona magnanima (HmL-45; Tortricidae) and Spodoptera frugiperda (Sf-9; Noctuidae). The responses were compared with those to a wider-host-range virus, Autographa californica NPV (AcMNPV). Each cell line was inoculated with one of the three viruses, and we monitored cell growth, viral DNA replication, and transcription of the viral genes ie-1, lef-8, vp39 and polh using PCR and RT-PCR. Occlusion bodies were not produced in any of the cell lines inoculated with AdhoNPV or AdorNPV, and were only observed in Sf-9 cells inoculated with AcMNPV after 48 hpi. Cell growth was not affected in cell lines administered with either AdhoNPV or AdorNPV, but was suppressed within 24 hpi in Sf-9 cells treated with AcMNPV. AcMNPV ie-1 transcription was detected in non-permissive AhL-83 and HmL-45 as well as in permissive Sf9 cells. However, no transcription of any gene tested, and no obvious DNA replication, was detected in any of the three cell lines treated with AdhoNPV or AdorNPV.

Regulation of *Bombyx mori* initiator caspase Dronc by Hycu-IAP3 of *Hyphantria cunea* nucleopolyhedrovirus

Motoko Ikeda[1], Ikue Suganuma[2], Michihiro Kobayashi[3]

[1]Nagoya University, Japan, [2]Nagoya University, Japan, [3]Nagoya University, Japan

A number of insect cells infected with nucleopolyhedroviruses (NPVs) undergo apoptosis as an anti-viral response. NPVs encode anti-apoptotic genes, such as Inhibitor of apoptosis (iap), p35 and p49, and suppress virus-induced apoptosis in host cells. Hyphantria cunea MNPV (HycuMNPV) encodes three iap genes, hycu-iap1, hycu-iap2 and hycu-iap3. Only hycu-iap3, but not hycu-iap1 and hycu-iap2, is an indispensable anti-apoptotic gene for productive infection of HycuMNPV in SpIm cells. To get insights into molecular mechanisms underlying apoptosis suppression by Hycu-IAP3, we have studied cellular factors that are involved in the induction of apoptosis. In this study, we cloned and characterized a Bombyx mori homolog of Drosophila initiator caspase Dronc, Bm-Dronc. Bacterially expressed Bm-Dronc preferred synthetic substrates of initiator caspase rather than those of effector caspase. An antibody was raised against the bacterially expressed Bm-Dronc, and changes of endogenous Bm-Dronc in BM-N cells during NPV infection were analyzed. In mock-infected BM-N cells, Bm-Dronc was detected as a full-length form. Apoptosis induction in BM-N cells by infection with p35-defective Autographa californica MNPV (vAcΔp35) promoted the cleavage of Bm-Dronc. To determine whether Hycu-IAP3 affected the endogenous Bm-Dronc, BM-N cells were transfected with hycu-iap3 and then infected with vAcΔp35. Both full-length and cleaved form Bm-Dronc decreased in Hycu-IAP3 expressing cells, indicating that Hycu-IAP3 reduced endogenous Bm-Dronc. This decrease of Bm-Dronc by Hycu-IAP3 was inhibited by a proteasome inhibitor, MG132, suggesting that Hycu-IAP3 promotes degradation of Bm-Dronc through ubiquitin-proteasome pathways.

Regional expression of the putative virus receptor, nsd-2, and the virus, BmDNV-2 in the midgut

Katsuhiko Ito[1], Sachiko Shimura[2], Keiko Kadono-Okuda[3]

[1]National Institute of Agrobiological Sciences (NIAS), Japan, [2]National Institute of Agrobiological Sciences (NIAS), Japan, [3]National Institute of Agrobiological Sciences (NIAS), Japan

Bombyx mori densovirus type 2 (BmDNV-2) is a pathogen of flacherie disease in the silkworm. BmDNV-2 replicates only in midgut columnar cells and causes fatal disease. The resistance expressed in some silkworm strains against the virus is determined by a single gene, nsd-2, which is characterized as nonsusceptibility irrespective of the viral dose. Previously we have identified nsd-2 by positional cloning and found that this gene encodes a putative amino acid transporter which may work as a receptor for BmDNV-2. In this study, we investigated the relationship between the BmDNV-2 infection and the part of the midgut expressing nsd-2. RT-PCR analysis with total RNA isolated from anterior, middle, and posterior parts of the midgut showed that nsd-2 was strongly expressed in posterior part of the midgut. In the anterior and middle parts, the expression levels of nsd-2 were very low and not-detected, respectively. On the other hand, the BmDNV-2-derived transcript was clearly detected in all parts of the midgut. There was no significant difference among the parts of the midgut. These results suggest that BmDNV-2 might infect with another mechanism independent to nsd-2 in the middle part of the midgut. There is little information regarding the host's own factors in insects, therefore, we expect that our result will contribute to understanding a novel infection mechanism of insect virus.

Molecular dissection of *Bombyx mori* nucleopolyhedrovirus cg30

Genki Ishihara[1], Toru Shimada[2], Susumu Katsuma[3]

[1]University of Tokyo, Japan, [2]University of Tokyo, Japan, [3]University of Tokyo, Japan

The baculovirus cg30 gene is present in the genomes of most Group I and II NPVs. CG30 contains a RING finger motif, which has been shown to be associated with a ubiquitin ligase activity. Also, a previous study in Autographa californica nucleopolyhedrovirus (AcMNPV) revealed that this gene is not essential for virus replication, and a cg30-desrupted virus did not show any significant differences compared with wild-type virus. To know the role of cg30 in other baculoviruses, we constructed a Bombyx mori nucleopolyhedrovirus (BmNPV) mutant (BmCG30D) lacking a functional cg30 by a LacZ cassette insertion, and characterized its infectivity in BmN cells and B. mori larvae. BmCG30D produced fewer budded viruses in BmN cells and occlusion bodies in B. mori larvae as compared with wild-type BmNPV, respectively. Larval bioassays also revealed that CG30 accelerates death of B. mori larvae. These results suggest that CG30 is required for efficient late and very late gene expression. We are currently characterizing two additional mutants, BmCG30CS and BmCG30RingD, both of which likely have no ubiquitin ligase activity. By clarifying the properties of these two mutants in virus-infected cells, we may elucidate the role of CG30-associated ubiquitin ligase activity during baculovirus infection.

Coexistence of full-length and truncated versions of ecdysteroid UDP-glucosyltransferase gene in the *Antheraea pernyi* nucleopolyhedrovirus isolated from *Samia cynthia ricini*

Kuni Sasaki[1], Yuan-jiao Huang[2], Mei-ling Shi[3], Xue-ying Wang[4], Jun Kobayahi[5]

[1]*Yamaguchi university, Japan,* [2]*Guangxi Medical University, China,* [3]*Guangxi Academy of Sericulture Sciences, China,* [4]*Shenyang Agricultural University, China,* [5]*Yamaguchi university, Japan*

The baculovirus ecdysteroid UDP-glucosyltransferase gene (egt) encodes an enzyme catalyzing the sugar conjugation of ecdysteroids to render them inactive. The infected larvae, therefore, have been voracious without moulting and metamorphosis, and produce a large amount of progeny virus. Because of this advantage, egt is conserved among lepidopteran baculoviruses with few exceptions, one of which is the Antheraea pernyi nucleopolyhedrovirus (AnpeNPV) isolated in Liaoning Province, China. Recently, we have found that another AnpeNPV isolated from Samia cynthia ricini in Guangxi Province, China, is a heterogeneous mixture of full-length and truncated versions of egt. Virus clones with truncated egt could not suppress moulting and metamorphosis of infected S. c. ricini larvae, and kill them ca. 5 days faster than a clone with full-length egt, demonstrating that the truncated versions do not encode any functional enzymes. Persistence of the truncated egt in two AnpeNPV populations in China indicates certain advantages of lacking the functional EGT, even with a lesser production of progeny virus. In addition, comparative sequence analysis has revealed that 5' UTR (including the N-terminal coding region), 3' UTR, and a short sequence (28 bp) in the middle of the coding region are conserved among all of the truncated versions, which seem to be transcribed in the infected A. pernyi cell line, suggesting the importance of the conserved regions for the virus. To understand reasons and roles of the truncated egt of AnpeNPV, further investigations of the host-virus interactions are now in progress.

Clonal variation in the *Helicoverpa armigera* insect cell population

Sudawan Chaeychomsri[1], Win Chaeychomsri[2]

[1]*Kasetsart University, Thailand,* [2]*Kasetsart University, Thailand*

A total of 16 clones were initially isolated by single-cell cloning from the established HAPO2 cell line derived from pupal ovarian tissue of the cotton bollworm, Helicoverpa armigera. Many of the isolates with highly vacuolated cytoplasms eventually died during subculturing. The 2 rapidly growing clonal cell lines, clones B-5 and D-4 were selected for further analysis. The clonal cell lines differed in their predominant morphology, and relative ability to support replication of the H. armigera nucleopolyhedrovirus (HearNPV). The B-5 and D-4 clonal cell lines were permissive to HearNPV exhibiting nuclear hypertrophy and occlusion bodies (OB) formation. However, the D-4 cell line was more susceptible to HearNPV infection than B-5 cell line, presenting higher infection level and high number of OB produced per cell. At late stages of infection, cell lysis and release of OB into the culture medium occurred in HearNPV-infected HAPO2 D-4 cells. The data described in this study indicate that clone D-4 will be a highly productive new clonal cell line that will be useful for the production of baculoviruses, recombinant protein expression in the baculovirus/insect cell system and other applications in biotechnology.

Mosquito vector control is an important part of controlling infectious diseases. Although the use of chemical insecticides is the mainstay for disease vector control, development of insecticide resistance has been reported. Now new vector control approaches are required. So, the aim of this study was to search promising isolates as fungal biopesticide of vector mosquito. Initially, entomopathogenic fungi were isolated from wild mosquito collected in Japan and Burkina Faso by two means of isolation methods (using the whole body of mosquito and the mosquito sterilized body surface), and molecular-based identification was conducted. As a result, Beauveria bassiana, B. brongniartii, Isaria farinosa, I. fumosorosea, Paecilomyces carneus, P. lilacinus, Lecanicillium araneicola, Lecanicillium spp., Simplicillium lamelicola and S. lanosoniveum were detected. Subsequently, these isolates were applied to bioassay against adult female Anopheles stephensi. Twenty seven isolates which showed higher pathogenicity and/or infectivity in preliminary experiment were evaluated the 50 % lethal time (LT50) and infection rate. As a result, LT50 values were ranged from 5.8 days to 12.5 days in isolates from whole mosquito body, and 6.6 days to 14.9 days in isolates from inside of the mosquito body, while, control plot was 16.6 days. Isolates from inside of the mosquito body showed tendency to lower virulence than isolates from whole mosquito body. Especially, Beauveria bassiana 60-2 showed highest virulence and infection rate against An. stephensi. So, our results suggested that wild adult mosquitoes have various entomopathogenic fungi that might have the potential for controlling vector mosquito as a biopesticide.

The large pine weevil (*Hylobius abietis*) as a vector of saprophytic fungi

Ivar Sibul[1], Tiia Drenkhan[2]

[1]*Estonian University of Life Sciences, Estonia,* [2]*Estonian University of Life Sciences, Estonia*

Saprophytic fungi Heterobasidion parviporum Niemela & Korhonen and H. annosum (Fr.) Bref are recognized as a major pathogenic saprophytic fungi of both young seedlings and mature trees, where they produce characteristic root and butt rot. Phlebiopsis gigantea (Fr.) Julich is a common saprophytic fungus that causes white rot of conifer logs and stumps. It is used as a biological control of annosum root rot, caused by Heterobasidion spp. The aim of this study was to investigate the large pine weevil (Hylobius abietis L.), an important pest of transplanted coniferous seedlings, capability to preserve alive in digestive tract the mycelium of fungi. In laboratory tests the mycelium of P. gigantea survived the most in viable condition through the digestive tract of the large pine weevil. In additional in pine weevils excrements were identified also the fungi of H. parvivorum. The vector insects were both males and females. Experiments showed that the large pine weevil could be the vector of pathogens Heterobasidion spp. and also for their natural enemy P. gigantea. The research was supported by the Estonian Science Foundation (grant numbers 6781 and 9449).

Genome and transcriptome-wide analysis of the immune-related genes in the brown planthopper *Nilaparvata lugens*

Yan-Yuan Bao[1], Dong Zhao[2], Li-Bo Chen[3], Hong-Yuan Jin[4], Liang-Min Xu[5], Chuan-Xi Zhang[6]

[1]Zhejiang University, China, [2]Zhejiang University, China, [3]Zhejiang University, China, [4]Zhejiang University, China, [5]Zhejiang University, China, [6]Zhejiang University, China

The brown planthopper (Nilaparvata lugens) is one of the most serious rice plant pests in Asia. BPH causes extensive rice damage by sucking rice phloem sap, which results in stunted plant growth and transmission of plant viruses. Little is known about the immunological mechanisms occurring in N. lugens. In this study, we performed the genome- and transcriptome-wide analysis of the immune-related genes via the next-generation high-throughput DNA sequencing technology. We identified a large number of genes encoding N. lugens pattern recognition proteins, modulation proteins, effectors and the molecules involved in the immune signaling pathways including Toll, Imd, JAK-STAT and JNK pathways. We investigated the gene expression profiles responded to the bacterial and viral infection at the transcript levels.

Identification of a new *Bombyx mori* nucleopolyhedrovirus strains and analysis of its bro gene family

Jiaping Xu[1], Jingbo Zhou[2]

[1]*Anhui Agricultural University, China,* [2]*Anhui Agricultural University, China*

The highly pathogenic Bombyx mori nucleopolyhedrovirus (BmNPV) has caused severe damages to sericulture in many countries, and the relationship between the pathogenicity of various BmNPV strains and their geographical evolution has been the topic of our interest. In this study, we isolated a new BmNPV strain from Thailand (BmNPV-Thai), based on the sequences of its conservative genes p10, p35, polh, egt and vp39. The obtained BmNPV appeared to have its baculovirus repeated ORF (bro) genes different from four other well-known BmNPV strains of China (GD, CQ1), Japan (T3) and France (SC7). Specifically, BmNPV-Thai has only the regions of bro-a, bro-c and bro-d, but not bro-b and bro-e genes. These bro genes of BmNPV are only localized in two subgroups which high homology to their counterparts and the encode BRO proteins differ mainly at their N-terminal amino acid residues. Phylogenetic analysis indicates that the evolution of the bro genes of the five BmNPV strains is not obviously associated with their geographic locations.

Isolation of *Bacillus thuringiensis* from forest environments in Korea

Dae-Weon Lee
KyungSung University, Republic of Korea

We investigated the distribution, toxicity, morphology, and protein profiles of Bacillus thuringiensis isolates from forests in Korea to isolate naturally occurring novel B. thuringiensis. A total of 170 B. thuringiensis isolates were obtained from 832 samples producing spore and parasporal inclusion bodies. In toxicity tests for lepidopteran, dipteran, and coleopteran insects, 57.6% isolates were toxic only to Lepidoptera, 5.3% were toxic only to Diptera, and 24.1% were toxic to both Diptera and Lepidoptera. The remaining collections (13.0%) were not toxic to the tested insects. The shapes of the parasporal crystals produced in B. thuringiensis isolates were bipyramidal, spherical, ovoid, or irregular. As their toxicities varied with parasporal crystal shape, B. thuringiensis isolates possessing bipyramidal or irregular parasporal crystals were largely toxic to lepidopteran species whereas those producing spherical parasporal crystals were mainly toxic to dipteran species. B. thuringiensis toxic to both dipteran and lepidopteran insects contained 130- and 70-kDa parasporal crystals, whereas B. thuringiensis toxic to lepidopteran insects expressed 130-kDa parasporal crystals. The results suggest that forest areas in Korea are a rich source of B. thuringiensis and need to be further explored to discover novel B. thuringiensis isolates.

Migrations and multiplications of three kinds of pine wood nematodes in *Pinus thunbergii*

Joung A Son[1], Yil-Sung Moon[2], Chan Sik Jung[3], Chul-Su Kim[4]

[1]Korea Forest Research Institute, Republic of Korea, [2]Korea Forest Research Institute, Republic of Korea, [3]Korea Forest Research Institute, Republic of Korea, [4]Korea Forest Research Institute, Republic of Korea

To ascertain the effects of migration and multiplication of pine wood nematodes (PWNs) in susceptible pine trees on pine wilt disease, pathogenic Bursaphelenchus xylophilus and non-pathogenic East Asian type and European type of B. mucronatus were inoculated on top cross-cut surfaces of 1-year-old stem cuttings of 5-year-old Pinus thunbergii seedlings. One thousand PWNs were inoculated on 20 cm pine stem cuttings and then the stem cuttings were cut into 2.5 cm segments on 1 and 5 days after inoculation and PWNs were extracted from each 2.5 cm segments to investigate distributions of pine wood nematodes. Also 200 PWNs were inoculated on 20 cm pine stem cuttings and Botrytis cinerea fungal mats and then they were extracted on 7 days after inoculation to measure increases of three kinds of pine wood nematode population. The distributions of pathogenic PWN of B. xylophilus in 20 cm pine stem cuttings were not significantly different from those of non-pathogenic PWNs of East Asian type and European type of B. mucronatus on 1 and 5 days after inoculation. The population growth rate of B. xylophilus on B. cinerea, however, was significantly higher than those of East Asian type and European type of B. mucronatus and the mean number of B. xylophilus remained in pine stem cuttings was also significantly higher than those of the other two PWNs. Thus pathogenicity of B. xylophilus is closely related to the multiplying ability rather than the migration ability compared with non-pathogenic East Asian type and European type of B. mucronatus.

High-throughput expression of recombinant protein using baculovirus

Jae Young Choi[1], Yang-Su Kim[2], Yong Wang[3], Xue Ying Tao[4], Qin Liu[5], Jong Yul Roh[6], Soo Dong Woo[7], Byung Rae Jin[8], Yeon Ho Je[9]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Lanzhou University, China, [4]Seoul National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Korea National Institute of Health, Republic of Korea, [7]Chungbuk National University, Republic of Korea, [8]Dong-A University, Republic of Korea, [9]Seoul National University, Republic of Korea

Recently, we constructed a novel recombinant baculovirus genome, bEasyBac, enabling easy and fast generation of pure recombinant baculovirus without any purification step. In the bEasyBac, bacteriophage lambda site-specific attachment (att) sites were introduced to facilitate the generation of recombinant viral genome by in vitro transposition. Moreover, extracellular RNase gene from Bacillus amyloliquefaciens, barnase, was expressed under the control of Cotesia plutellae bracovirus (CpBV) ORF3005 early promoter to negatively select against non-recombinant background. The bEasyBac could replicate in host insect cells only when the barnase gene was replaced to gene of interest by in vitro transposition. Insect cells transfected with the bEasyBac not only showed slightly cytopathic effects with reduced cell growth after transfection but also did not support any viral replication. When the bEasyBac was transposed with pDualBac-EGFP and the EGFP expression efficiency along passage was investigated, the resulting recombinant virus, EasyBac-EGFP, showed comparable level of EGFP expression efficiency with the plaque-purified recombinant virus, AcEGFP, which was constructed using bAcGOZA system, whereas, the non-purified AcEGFP showed quite reduced level of EGFP along passages. Moreover, no non-recombinant backgrounds were detected from unpurified EasyBac-EGFP stocks. Based on these results, high-throughput condition for generation of multiple recombinant viruses in a time was established. These results suggest that the bEasyBac has an effective benefit enabling for high-throughput baculovirus expression vector without purifying recombinant virus.

Molecular characterization of a *Bacillus thuringiensis* serovar mogi (flagellar serotype 3a3b3d) with mosquitocidal activity

Qin Liu[1], Jong Yul Roh[2], Jae Young Choi[3], Yong Wang[4], Xue Ying Tao[5], Joo Hyun Lee[6], Song Eun Kim[7], Zhenli Fu[8], Jae Su Kim[9], Yeon Ho Je[10]

[1]Seoul National University, Republic of Korea, [2]Korea National Institute of Health, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]Lanzhou University, China, [5]Seoul National University, Republic of Korea, [6]Seoul National University, Republic of Korea, [7]Seoul National University, Republic of Korea, [8]Seoul National University, Republic of Korea, [9]Chonbuk National University, Republic of Korea, [10]Seoul National University, Republic of Korea

Plasmids from Bacillus thuringiensis have been implicated in pathogenicity as they carry the genes responsible for different types of diseases in mammals and insects. B. thuringiensis serovar mogi of a novel serogroup (H3a3b3d), which showed mosquitocidal activity against Anopheles sinensis and Culex pipiens pallens, was isolated from fallen leaves in Mungyeong city, Republic of Korea. In contrast to the complicated plasmid profiles of B. thuringiensis H3 serotype strains, the B. thuringiensis serovar mogi contained only megaplasmid (> 30 MDa) on which the toxin genes were occasionally located. Sequence analysis using 454-pyrosequencing revealed that the megaplasmid harbored at least seven putative cry genes, showing about 84%, 75%, 73%, 58%, 84%, 39% and 75% similarities in amino acid sequences with Cry27Aa, Cry19Ba, Cry20-like, Cry56Aa, Cry39ORF2, Cry8Ba and Cry40ORF2, respectively. These cry genes were cloned to the Escherichia coli-B. thuringiensis shuttle vector, pHT1K, and then introduced into an acrystalliferous B. thuringiensis Cry-B strain for further molecular characterization. This novel 3a3b3d type strain, B. thuringiensis serovar mogi, could be used as a good resource for studying unknown mosquitocidal cry genes.

Functional characterization of *Autographa californica* multiple nucleopolyhedrovirus ORF43

Xue Ying Tao[1], Jae Young Choi[2], Yong Wang[3], Jong Yul Roh[4], Joo Hyun Lee[5], Qin Liu[6], Jong Bin Park[7], Jae Su Kim[8], Soo Dong Woo[9], Byung Rae Jin[10], Yeon Ho Je[11]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Lanzhou University, Republic of Korea, [4]Korea National Institute of Health, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Seoul National University, Republic of Korea, [7]Seoul National University, Republic of Korea, [8]Chonbuk National University, Republic of Korea, [9]Chungbuk National University, Republic of Korea, [10]Dong-A University, Republic of Korea, [11]Seoul National University, Republic of Korea

ORF43 (ac43) of Autographa californica multiple nucleopolyhedrovirus (AcMNPV) is a highly conserved baculovirus gene whose function is unknown. To determine the role of ac43 in baculovirus life cycle, we constructed an ac43-deleted mutant AcMNPV, Ac43KO. After transfection into Spodoptera frugiperda cells, Ac43KO produced polyhedra with much larger size compared to those of wild-type AcMNPV. Interestingly, some of nucleocapsids were singly enveloped in the polyhedrin matrix while the nucleocapsids of AcMNPV have been known to be multiply enveloped. Furthermore, Ac43KO led to a defect in transcription and expression of polyhedrin, which resulted in less occlusion body (OB) production. However, Ac43KO did not affect production of budded virus (BV) since there was no remarkable difference in BV titer. These results suggest that ac43 plays an important role in expression of polyhedrin, morphogenesis of OB and assembly of virions occluded in OB.

Keywords:*AcMNPV, ac43, knockout mutant, OB morphogenesis, nucleocapsid packaging*

Novel baculovirus expression vector enabling simple purification of recombinant protein using polyhedrin fusion

Jong Yul Roh[1], Jae Young Choi[2], Joong Nam Kang[3], Yong Wang[4], Hee Jin Shim[5], Qin Liu[6], Xue Ying Tao[7], Hong Guang Xu[8], Soo Dong Woo[9], Byung Rae Jin[10], Yeon Ho Je[11]

[1]Korea National Institute of Health, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]Lanzhou University, China, [5]Seoul National University, Republic of Korea, [6]Seoul National University, Republic of Korea, [7]Seoul National University, Republic of Korea, [8]Seoul National University, Republic of Korea, [9]Chungbuk National University, Republic of Korea, [10]Dong-A University, Republic of Korea, [11]Seoul National University, Republic of Korea

Previously, we found that expression by translational fusion of the polyhedrin (Polh)-green fluorescence protein (GFP) led to the formation of granular structures and these fluorescent granules were easily precipitated by high-speed centrifugation. Here, we developed an easy, fast, and mass purification system using this baculovirus expression system (BES). An enhanced GFP (EGFP) fused with Polh gene at the N-terminus including an adaptor and enterokinase (EK) site between Polh and EGFP was expressed in Sf9 cells. The cells infected by AcPolhEKA-EGFP produced fluorescent granules. The EGFP fusion protein was purified from granule-containing cells according to three steps; cell harvest, sonication and EK digestion. Through the final enterokinase digestion, EGFP was presented mainly in the supernatant (93.3%) and the supernatant also showed a pure EGFP band. These results suggest that the combined procedure of Polh fusion expression and enterokinase digestion can used for the rapid and easy purification of other proteins.

Keywords:*polyhedrin fusion, granulation, EGFP, baculovirus expression system, easy purification system*

Cloning of circular DNAs from microorganisms using a novel plasmid capture system

Jong Yul Roh[1], Yong Wang[2], Qin Liu[3], Xue Ying Tao[4], Jae Young Choi[5], Hee Jin Shim[6], Hong Guang Xu[7], Soo Dong Woo[8], Byung Rae Jin[9], Yeon Ho Je[10]

[1]Korea National Institute of Health, Republic of Korea, [2]Lanzhou University, China, [3]Seoul National University, Republic of Korea, [4]Seoul National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Seoul National University, Republic of Korea, [7]Seoul National University, Republic of Korea, [8]Chungbuk National University, Republic of Korea, [9]Dong-A University, Republic of Korea, [10]Seoul National University, Republic of Korea

Plasmid capture system (PCS) was developed for easy cloning and manipulation of circular double-stranded DNA from various sources. Recently, we improved PCS system (named PCS-LZ) to clone relatively large-sized DNA molecules (30~150 kb). PCS-LZ donor consists of a Mini-F replicon and a kanamycin resistance marker between Tn7L and Tn7R regions. Both replicon and marker gene of PCS-LZ donor are transferred into target plasmid DNAs by in vitro transposition and the transposed DNAs can replicate in E. coli cells by transformation. White/blue screening by LacZ expression is also available to avoid backgrounds. Up to now, we acquired various circular DNA clones from four sources such as plasmids of B. thuringiensis, bacteriophage genome isolated from B. thuringiensis, genome segments of Cotesia glomerata bracovirus, and polymorphic genomes of Autographa californica nucleopolyhedrovirus. Conclusively, we expect this PCS-LZ system would be a powerful tool for genomic analysis and mutagenesis study at the area of invertebrate pathology and further its application will be enlarged to the vertebrate pathology area.

Keywords:*plasmid capture system (PCS), PCS-LZ, in vitro transposition, circular DNA cloning, Bacillus thuringiensis, CgBV, AcMNPV*

A Novel, highly effective and environmentally friendly recombinant baculovirus insecticide, NeuroBactrus

Hee Jin Shim[1], Jae Young Choi[2], Yong Wang[3], Xue Ying Tao[4], Qin Liu[5], Jong Yul Roh[6], Jae Su Kim[7], Soo Dong Woo[8], Byung Rae Jin[9], Yeon Ho Je[10]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Lanzhou University, China, [4]Seoul National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Korea National Institute of Health, Republic of Korea, [7]Chonbuk National University, Republic of Korea, [8]Chungbuk National University, Republic of Korea, [9]Dong-A University, Republic of Korea, [10]Seoul National University, Republic of Korea

A novel recombinant baculovirus, NeuroBactrus, was constructed to develop an improved baculovirus insecticide with additional beneficial properties, such as a higher insecticidal activity and improved recovery, compared to wild-type baculovirus. For the construction of the NeuroBactrus, the Bacillus thuringiensis cry1-5 crystal protein gene was introduced into the Autographa californica nucleopolyhedrovirus (AcMNPV) genome by fusion of polyhedrin-cry1-5-polyhedrin under the control of the polyhedrin promoter. In the opposite direction, an insect-specific neurotoxin gene, AaIT, from Androctonus australis was introduced under the control of an early promoter from Cotesia plutellae bracovirus by fusion of a partial fragment of orf603. The Polyhedrin-Cry1-5-Polyhedrin fusion protein expressed by the NeuroBactrus was not only occluded into the polyhedra, but it was also activated by treatment with trypsin, resulting in an approximately 65-kDa active toxin. In addition, qrt-PCR revealed that the neurotoxin was expressed from the early phase of infection. The NeuroBactrus showed a high level of insecticidal activity against Plutella xylostella larvae and a significant reduction in the median lethal time (LT50) against Spodoptera exigua larvae compared to those of wild-type AcMNPV. Re-recombinant mutants derived from NeuroBactrus in which AaIT and/or cry1-5 were deleted were generated by serial passages in vitro. Expression of the foreign proteins (Bt toxin and AaIT) was continuously reduced during the serial passage of the NeuroBactrus. Moreover, polyhedra collected from S. exigua larvae infected with the serially passed NeuroBactrus showed insecticidal activity similar to that of wild-type AcMNPV. These results suggested that the NeuroBactrus could be recovered to wild-type AcMNPV through serial passaging.

Keywords:*recombinant baculovirus, insecticide, Bacillus thuringiensis, AaIT, recovery to wild-type*

Incidence of entomopathogenic fungi from agricultural and forest areas and their pathogenicity in *Bactrocera cucurbitae* (Coquillett) (Diptera: Tephritidae) in Southern Thailand

Narit Thaochan[1], Anuchit Chinajariyawong[2]

[1]*Prince of Songkla University, Thailand,* [2]*National Biological Control Research Center Central Regional Center, Thailand*

Southern Thailand located on the Malay Peninsula is rich of fauna and flora in nature. Diversity of microorganisms concerning microbial control of insect pests is also well off. Therefore, an initial research project was designed to collect and isolate entomopathogenic fungi from soil and insect cadavers in areas of agriculture and forest. Sixty-six isolates of entomopathogenic fungi were obtained comprising 64 isolates of Metarhizium anisopliae and two isolates of Beauveria bassiana. Fifty eight were isolated from soil and eight from insect cadavers (six isolates of M. anisopliae and two of B. bassiana). The soil samples from Songkhla province gave the highest number of entomopathogenic fungi (39 isolates) followed by the soil samples from Patthalung province (14 isolates). In contrast, the soil samples from Nakhon Si Thammarat province had the lowest number (5 isolates). The entomopathogenic fungi were divided into 4 groups according to their mycelial growth and sporulation. Later the isolated entomopathogenic fungi were assessed for their pathogenicity in adult fruit fly, Bactrocera cucurbitae (Coquillett). Each isolates caused significantly different degrees of virulence on the flies, with M. anisopliae isolate PSUM05 giving 100% mortality of adult male and female within 5 and 7 days. Extending observation up to 15 days, although B. bassiana could induce mortality of the adult flies, mortality in the flies was less than 56%.

Keywords:*entomopathogenic fungi, Metarhizium anisopliae, Beauveria bassiana, pathogenicity*

Real-time tracing of AcMNPV infection to Plutella xylostella and the interaction between virus and parasitoid

Shu-Jen Tuan[1], Yu-Chan Chao[2], Roger F. Hou[3]

[1]National Chung Hsing University, Taiwan, [2]Academia Sinica, Taiwan, [3]National Chung Hsing University,

Baculovirus is an important microorganism for controlling insect pests in the field, and is also crucial for integrating into an ecologically sound IPM program. In order to trace baculovirus infection, a recombinant baculovirus, vAcGFP, derived from Autographa californica nucleopolyhedrovirus (AcMNPV) was constructed. This virus contains a wt polyhedrin gene and a GFP coding region driven by p10 promoter. The LC50 values of vAcGFP and wt AcMNPV to the 3rd instar larvae with the diet incorporation method were 34.4 and 25.6 OBs/mm3 of diet, respectively. The LT50 values of these two viruses were relatively close. The larvae infected with vAcGFP were easily detectable due to the emittion of green fluorescence (505nm) as irradiated by a 365nm UV light. Its FT50 (50% fluorescense-emitting time) was 65 h earlier than LT50 at 763 OBs/mm3. The 3rd instar larvae of P. xylostella were inoculated with vAcGFP and simultaneously parasitized by the parasitoid, Cotesia plutellae. A fluorescence-emitting rate of 84 and 32% was separately coupled with 12 and 54% cocooning rate at 76.3 and 7.6 PIBs/mm3, respectively, and only 5~8% cocoons with fluorescence was detected. The cocooning rate of C. plutellae was decreasing through the time of parasitism and the increasing of viral concentration. In conclusion, GFP could be used as a specific and non-destroying biomarker for detection of insect dynamics after being infected with NPV in the field. In addition, our study shed a light for further study of the complicated interactions between baculovirus and broconid wasp in an insect host.

Synergistic interaction of *Beauveria bassiana* and *Bacillus thuringiensis* for the control of tomato fruitworm *Helicoverpa armigera*

Mirza Abdul Qayyum[1], Waqas Wakil[2], Usman Ghazanfar[3], Yong Jung Kwon[4]

[1]University of Agriculture Faisalabad, Pakistan, [2]University of Agriculture Faisalabad, Pakistan, [3]University of Sargodha, Pakistan, [4]Kyungpook National University, Republic of Korea

Toxicity of commercial formulation of Bacillus thuringiensis and Beauveria bassiana was evaluated against second instar larvae of tomato fruitworm Helicoverpa armigera collected from different major tomato growing districts in Punjab, Pakistan viz-a-viz Khanewal, Multan, Muzaffar Garh, Bahawalpur and Pakpattan. Larval development was greatly reduced when toxin concentration in diet increased from lower to higher concentration. The mortality increased with increase in application rate of either B. bassiana or Bt while significantly high mortality (100.00±0.00) was recorded in Pakpattan population for the combined use of Bt and B. bassiana. Combination of lower dose of B. bassiana (1×106 conidia/ml) with both concentrations of Bt showed additive effect on mortality of H. armigera while higher dose of B. bassiana (1×107 conidia/ml) synergistically enhanced mortality in all localities. Lowest pupation (0.00±0.00) rate was observed in simultaneous application of higher concentration of Bt and B. bassiana (1×107spores/ml+1µg/g Bt) which showed highest mortal effect on larvae of H. armigera. Rate of mycosis was predominantly high in larvae found dead in individual application of B. bassiana and certainly no salmon color change was found in larvae died with B. thuringiensis.

Entomopathogenic fungi: An alternative in the control of the Asian citrus psyllid, *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae)?

Hana Haji Allahverdi Pour

Iranian Research Institute of Plant Protection, Iran

The Asian citrus psyllid, Diaphorina citri Kuwayama, is a vector of Candidatus Liberibacter asiaticus which causes citrus greening disease. This has become the most damaging disease of citrus trees In Iran since its first incidence in 2007. Controlling the vector is the most efficient approach for controlling this disease. Entomopathogenic fungi can be useful alternatives to control the vector. Two fungal isolates, Metarrhizium anisopliae ('DEMI 002') and Paecilomyces tenuipes ('DEPI 002') were assessed against adult psyllids in the laboratory. To study their mortalities and the effect of sprayed area on mortality, a detached-leaf bioassay was used. Four leaf sections were placed together in a Petri dish and one to four of them were sprayed by the fungal suspensions at a concentration of 7×105 spores/ml. A single adult was released into each Petri dish (27±2 ?C, 75% RH). Five days after treatment, 'DEMI 002' and 'DEPI 002' caused 71% and 29% mortalities, respectively. 'DEMI 002' was significantly more effective ($F = 6.88$; $df = 4, 23$; $P < 0.05$) than 'DEPI 002'; However, there was no statistical difference between different leaf area coverage. More studies under greenhouse and field conditions are required.

Antimicrobial and antioxidant activity in liquid culture filtrates of entomopathogenic fungi

Tae Young Shin[1], Won Woo Lee[2], Jae Bang Choi[3], Sung Min Bae[4], Yeon Ho Je[5], Byung Rae Jin[6], Soo Dong Woo[7]

[1]Chungbuk National University, Republic of Korea, [2]Chungbuk National University, Republic of Korea, [3]Chungbuk National University, Republic of Korea, [4]Chungbuk National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Dong-A University, Republic of Korea, [7]Chungbuk National University, Republic of Korea

The entomopathogenic fungi were an important natural pathogenic of insects that has been developed as potential biological control agents for many important agricultural, forest and medical pests. Several these fungi produce a wide range of secondary metabolites with high therapeutic value as antibiotics, cytotoxic substances, insecticides, compounds that promote or inhibit growth, attractor and repellent. Therefore, this study was performed to select the antibacterial against two pathogenic bacteria including Ralstonia solanacearum and Escherichia coli and antioxidant activity of liquid culture filtrates of 347 entomopathogenic fungi form Korea soils using novel method which represents a quick and easily applicable tool obtaining large number of samples. As results, seventy-two isolates (20%), twenty-two isolates (6%) and twenty-two isolates (6%) of these fungal metabolites produced anti-R. solanacearum, anti-E. coli and 1,1-diphenyl-2-picrylhydrazyl (DPPH) radicals scavenging activity compounds, respectively. The preferential antibacterial and radical scavenging activity gives evidence that these entomopathogenic fungal metabolites might be useful as a source for bacteria control and pharmaceutical interest

Genomic sequence analysis of the *Hyphantria cunea* granulovirus isolated in Korea

Jaebang Choi[1], Won Il Heo[2], Sung Min Bae[3], Tae Young Shin[4], Yeon Ho Je[5], Byung Rae Jin[6], Soo Dong Woo[7]

[1]Chungbuk National University, Republic of Korea, [2]Chungbuk National University, Republic of Korea, [3]Chungbuk National University, Republic of Korea, [4]Chungbuk National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Dong-A University, Republic of Korea, [7]Chungbuk National University, Republic of Korea

Hyphantria cunea is a fall webworm is considered an agricultural pest. It is a major pest of many board-leaved trees. To better understand Hyphantria cunea granulovirus (HcGV), the nucleotide sequence of the HcGV DNA genome was determined and analyzed. HcGV isolated from naturally infected Hyphantria cunea larvae in Korea. The full genome sequence of HcGV were determined, analyzed and compared to those of other baculoviruses. The entire nucleotide sequence of the HcGV genome was fully sequenced using 454 pyrosequencing. The HcGV genome consisted of 114,557 bp and had on overall G+C content of 39.30%. Computer- assisted analysis predicted 130 open reading frames (ORFs) of 50 amino acids or greater that showed minimal overlap. HcGV shares more than 106 ORFs with other baculoviruses. The positions of at least some baculovirus homologous repeat regions appear to be conserved relative to specific baculovirus genes. The gene parity plot analysis, percent identity of the gene homologues and a phylogenetic analysis suggested that HcGV is betabaculovirus that is closely related to Xestia c-nigrum granulovirus but with a highly distinct genomic organization.

Keywords:*HcGV, Hyphantria cunea, 454 pyrosequencing*

Genetic expression characteristics of other nematodes cellulase-related genes except for *Bursaphelenchus xylophilus*.

Dahyun Moon[1], Yil-Sung Moon[2], Hyerim Han[3], Chansik Jung[4], Chulsu Kim[5]

[1]Korea Forest Research Institute, Republic of Korea, Republic of Korea, [2]Korea Forest Research Institute, Republic of Korea, Republic of Korea, [3]Korea Forest Research Institute, Republic of Korea, [4]Korea Forest Research Institute, Republic of Korea, [5]Korea Forest Research Institute, Republic of Korea

Bursaphelenchus xylophilus(Pine wood nematode, PWN) has been recognized as a casual pathogen of pine wilt disease (PWD). Bursaphelenchus xylophilus induce PWD as feed on plant cells ? consist of cellulose as parenchyma tracheids. Pine wilt disease is the one of serious forest disease in Korea so that conducted various mechanical and chemical researches for control damages, but insufficient as biotechnical researches. Some researches have suggested that Bursaphelenchus xylophilus secretes highly active cellulase in order to break down the cell walls and cell membranes of parenchyma tracheids. The results of previous studies have indicated that the cellulase of PWN performs a crucial function in these pathogenic substrances. Other nematodes as Busaphelenchus genus have speculated taken cellulase but not developed yet except for PWN. If other nematodes cellulase characteristics develop biotechnically except for PWN, contribute to research of Bursaphelenchus have been controversies about pathogenic. Therefore nematodes as Busaphelenchus genus ? Bursaphelenchus xylophilus, B. mucronatus(East asian type), B. mucronatus(European type), B. doui, B. thailadae, B. hylobianum, B. tusciae, B. yongensis ? grown on a lawn of Botrytis cinerea cultured on PDA media, extracted total RNA and synthesized cDNA. PWD cellulose related gene screened by NCBI (http://www.ncbi.nlm.nih.gov/) ? ACD12136.1, BAD34543.1, BAD34544.1, BAD34545.1, BAD34546.1, ACM44321.1, ACM44322.1, ACM44323.1 and compared with each other. Primers designed different site of the conserved domain after multiple sequence alignment and genetically compared with 8 Bursaphelenchus by RT-PCR.

Sequence analysis and characterization of adaptor protein MyD88 from a coleopteran beetle, *Tenebrio molitor*

Hongray Howrelia Patnaik[1], Bharat Bhusan Patnaik[2], Dong Hyun Kim[3], Seongmin Kang[4], Yong Seok Lee[5], Bok-Leul Lee[6], Nam Jeong Kim[7], Yeon soo Han[8]

[1]Chonnam National University, Republic of Korea, [2]Chonnam National University, Republic of Korea, [3]Chonnam National University, Republic of Korea, [4]Pusan National University, Republic of Korea, [5]Inje University, Republic of Korea, [6]Pusan National University, Republic of Korea, [7]National Academy of Agricultural Science, RDA, Republic of Korea, [8]Chonnam National University, Republic of Korea

MyD88 considered as an adaptor protein forms a major component of the Toll pathway during the response to fungal and Gram-positive bacterial infections and is recruited by the cleaved Spatzle-Toll complex. This is because; the Toll family in insect models studied and a similar family of Toll-like receptors (TLRs) identified in mammals signals to NF-κB through the adaptor, MyD88 that binds to the kinase Pelle in degrading Cactus, inducing the translocation of transcription factors, Dif and Dorsal, thus inducing the effector molecules. In an attempt to study the involvement of MyD88 as an integrator of signals from Toll, the full length cDNA of MyD88 have been cloned from the coleopteran beetle, Tenebrio molitor. Full-length sequence of MyD88 annotated by DNASTAR program reveals an open reading frame of 1172 bp encoding 391 amino acids. It has a 5'- and 3'-untranslated region of 83 bp and 300 bp respectively with polyA-tail comprising of 19bp starting from nucleotide no. 1557. BLAST and Multiple Alignment results have been conducted on MyD88 protein sequence, and it has been observed that it has significant sequence similarity with MyD88 of Tribolium castaneum. Putative conserved domains include an NH2-terminal death domain and COOH-terminal Toll-IL-1R domains that are implicated in interacting with Toll receptor family. The C-terminal sequences of MyD88 from closely-related groups indicate the uniqueness and less-conserved nature, a potent strategy for future development of antibodies with high-end specificity.

Cloning and expression pattern of a galectin homologue from a coleopteran insect, *Tenebrio molitor*

Hyo Jeong Lee[1], Gi Won Seo[2], Jeong Hwan Seong[3], Dong Hyun Kim[4], Seongmin Kang[5], Yong Hun Jo[6], Yong Seok Lee[7], Bok-Leul Lee[8], Nam Jeong Kim[9], Yeon soo Han[10]

[1]Chonnam National University, Republic of Korea, [2]Chonnam National University, Republic of Korea, [3]Chonnam National University, Republic of Korea, [4]Chonnam National University, Republic of Korea, [5]Pusan National University, Republic of Korea, [6]Pusan National University, Republic of Korea, [7]Inje University, Republic of Korea, [8]Pusan National University, Republic of Korea, [9]National Academy of Agricultural Science, RDA, Republic of Korea, [10]Chonnam National University, Republic of Korea

Galectin has been known to play a key role in insect innate immunity and pathogen recognition process. From the expressed sequence tags (ESTs) of T. molitor larvae, we have identified a galectin homologue (TmGalectin). The cDNA contained a 3′ untranslated region of 165 nucleotides, including a stop codon (TAA) and a poly (A) tail although 5'-UTR is not currently available. It consists of 660 bp with an open reading frame of 495 bp, encoding 164 amino acids. The deduced amino acid sequence of TmGalectin has relatively low identities (50%) to various insect galectin. Developmental expression analysis shows that TmGalectin is highly expressed during the pupal stages (day 2 and 5). Most interestingly, TmGalectin mRNA is highly expressed in adult integument and gut. Furthermore, TmGalectin mRNA was highly induced after immune-challenging with various immune elicitors such as Lys/DAP-type peptidoglycan (PGN), Beta 1,3 glucan, and Acholeplasma lyaste. These data suggests that TmGalectin may play a role in innate immune responses although it remains to further elucidate the precise biological functions in T. molitor.

Cloning and in silico analysis of spatzle 7 homologue from a coleopteran insect, *Tenebrio molitor*

Soogon Kim[1], Dong Hyun Kim[2], Yong Seok Lee[3], Bok-Leul Lee[4], Nam Jeong Kim[5], Yeon soo Han[6]

[1]Chonnam National University, Republic of Korea, [2]Chonnam National University, Republic of Korea, [3]Inje University, Republic of Korea, [4]Pusan National University, Republic of Korea, [5]National Academy of Agricultural Science, RDA, Republic of Korea, [6]Chonnam National University, Republic of Korea

Spatzle has been known to play a key role in Toll signaling cascade in response to gram-positive bacterial and fungal infection in insects. From the expressed sequence tags (ESTs) of T. molitor larvae, we have identified a spaztle homologue (TmSpatzle7). The cDNA contained a 3′ untranslated region of 112 nucleotides, including a stop codon (TAA) and a poly (A) tail although 5'-UTR is not currently available. It consists of 742 bp with an open reading frame of 630 bp, encoding 209 amino acids. The deduced amino acid sequence of TmSpatzle7 has relatively low identities (50%) to Tribolium castaneum Spatzle7, and also with T. castaneum spaetzle 1B (28%) and Aedes aegypti sp. Currently, TmSpaztle7 is expressed in pET expression vector to isolate recombinant TmPGRP-LE. Since spaztle 7 has not been fully characterized until now, expression and functional analysis will be conducted in response to various immune elictors and it still remains to further elucidate the precise biological functions of TmSpatzle7 in T. molitor.

Peptidoglcan recogniatioin protein-LE (PGRP-LE) plays a key role in immune deficiency (IMD) signaling cascade in response to gram-negative bacterial infection in insects including Drosophila and Tenebrio. From the expressed sequence tags (ESTs) of T. molitor larvae, we have identified a PGRP-LE homologue (TmPGRP-LE). The cDNA contained a 5′ untranslated region of 116 nucleotides and a 3′ untranslated region of 72 nucleotides, including a stop codon (TAA) and a poly (A) tail. It consists of 1,181 bp with an open reading frame of 993 bp, encoding 330 amino acids. The deduced amino acid sequence of TmPGRP-LE has relatively low identities (68%) to Tribolium castaneum PGRP-LE. Currently, TmPGRP-LE is expressed in pET expression vector to isolate recombinant TmPGRP-LE. Expression analysis will be conducted in response to various immune elictors and it still remains to further elucidate the precise biological functions of TmPGRP-LE in T. molitor.

Keywords:*PGRP-LE, Tenebrio, Innate Immunity*

Proteases are found in a wide range of organisms including bacteria, fungi and so on. Some of them were identified as virulence factors and have important roles in pathogenesis. In our previous work, Serratia liquefaciens Kuo1-1 isolated from ant lion larvae was highly virulent to two insect species, the silkworm, Bombyx mori and the American cockroach, Periplaneta americana. It was demonstrated that S. liquefaciens FK01, spontaneous a nalidixic acid-resistant mutant of Kuo1-1, produced two proteases. The proteases were determined to be metalloproteases upon inhibition test with specific metalloproteinase inhibitor EDTA. Zymography revealed that molecular masses were approximately 50 kDa. These results indicated that these proteases belonged to serralysin family. The genes encoding the proteases were cloned and designated ser1 and ser2. Conserved regions including a zinc binding motif (HEXXHXUGUXH), glycine-rich repeats (GGXGXD) and an ABC exporter motif (DXXX) were found in both Ser1 and Ser2 encoded by ser1 and ser2, respectively. To ascertain the toxicity to insects, recombinant proteins were produced in Escherichia coli BL21 DE3 (pLysS). The region corresponding to the putative mature proteins were amplified by PCR. The amplicons were cloned into the IPTG-inducible pET16b by In-Fusion technology. The recombinant proteins (rSer1 and rSer2) induced by IPTG were observed in insoluble inclusion bodies. The insoluble recombinant proteins were solubilized by 8 M urea, and then purified by His-tag affinity chromatography. The eluted proteins were dialyzed against buffer containing 0.1 mM EDTA. The zymography revealed that both rSer1 and rSer2 had strong proteolytic activities.

Pseudomonas aeruginosa, known as the human opportunistic pathogen, is a Gram-negative bacterium ubiquitously present in the environment. P. aeruginosa infects to not only the mammalian hosts, but also many organisms including the insect. In the mammalian hosts, infection mechanisms of the bacterium have been well investigated, and many important virulence factors have been identified. The infection mechanisms in the insects, however, remain unclear. In this study, we aimed to identify the important virulence factor in the insect hosts. Bacterial pathogens frequently use secreted protein to mediate interaction with their hosts. To investigate what protein is critical virulence factor for the insect, we constructed mutant strains of P. aeruginosa deficient in protein secretion systems (SSs) and assessed the virulence. P. aeruginosa has 5 type SSs including type I, II, III, V and VI. Until now, two SS-deficient mutants (type I SS, Apr pathway and type II SS, Hxr pathway) were constructed by replacing genes encoding SS with a gene cassette. The cassette contained a gentamicin resistance and a gfp gene, with both marker genes being flanked by Flp recombinase target sites. Subsequently, the cassette was excised with Flp recombinase and we obtained the markerless mutants. The assessing of virulence was carried out by inoculation with these mutants to the silkworm, Bombyx mori. The mutant strains did not show significantly decreased virulence to B. mori. This result indicated that the proteins secreted through type I SS Apr and type II SS Hxr pathway did not contribute in the virulence to B. mori.

Interaction of *Xenorhabdus nematophila* with *Bacillus thuringiensis* HD-73 against Bt-resistant *Plutella xylostella*

Qinying Wang[1], Yunyan Yang[2]

[1]*College of Plant Protection, China,* [2]*College of Plant Protection, China*

Abstract: Xenorhabdus nematophila HB310 strain is an insect pathogen that is mutualistic with entomopathogenic nematode Steinernema carpocapsae.The oral insecticidal activities of the culture broth from X. nematophila HB310 to Bt-susceptible and Bt-resistant population of Plutella xylostella were determined by the method of leaves-tip bioassays. The results showed that the toxicity of Bacillus thuringiensis (Bt) HD-73 and Bt HD-1 to resistant population was 105.43 times and 30.70 time of susceptible population of P. xylostella larvae. However, the toxicity of X. nematophila HB310 to resistant population just only was 0.92 time of susceptible population of P.xylostella. After investigating the synergistic action between X. nematophila HB310 and Bt HD-73, we found that there was significant synergistic action of Bt HD-73 on X. nematophila HB310 against Bt-susceptible and Bt-resistant larvae of P. xylostella , however, there was not the synergistic action of Bt HD-73 on X.nematophila HB310 against Bt-susceptible and Bt-resistant larvae of P. xylostella. These results demonstrated that there was not interactive resistance between X. nematophila and Bt Hd-73 , and the insecticidal mechanism X. nematophila maybe different from that of Bt HD-73.

The effect of entomopathogenic fungi, *Beauveria bassiana* (Balsamo) *Vuillemin* and *Lecanicillium muscarium* (Zimmerm.) Zare & W. Gams (Hyphomycetes: Moniliales), on mortality rate of cotton whitefly nymph

Ahmad Baghdadi[1], Kimia Kouhestani[2]

[1]*PayamNoor University, Iran,* [2]*Tehran University, Iran*

Bemisia tabaci is a worldwide pest causing yield loss in many economically important agricultural products in green houses and open fields. Chemical control provides only short-term solutions. Moreover, the overuse of pesticides, in controlling insects, has provoked the development of resistance to insecticides. pathogenicity of Beauveria bassiana (Balsamo) Vuillemin strain DEI001 , Lecanicillium muscarium (Zimmerm.) Zare & W. Gams strain DAOM 198499 and their combinations were investigated against second instar nymphs and adults of Cotton whitefly, Bemisia tabaci Gennadius under laboratory condition. The inoculum concentrations of conidia that deposited on under sides of leaves surface were 104-108 conidia/ml and sterile distilled water with 0.04% Tween 80 (Merck) as control. Second instar nymphs were selected through stereomicroscopic observations approximately 2 weeks after adult's removal. Applications of fungi were performed with a hand held sprayer. Three or four replicates were performed per treatments. Incubation was in Binder KBWF germinator regulated to 23 ± 1° C, 95 ± 5% and 16: 8 hours (L: D) photoperiod. Assessments of dead nymphs were performed daily for 10 days after treatment. LC50s were 4.4 × 105, 1.8 × 105 and 7.9 × 105 conidia / ml with 95% confidence for B. bassiana, L. muscarium and their interaction respectively. LT50s were 4.8, 6 and 8.3 days at 108, 107 and 106 conidia/ml for B. bassiana; 3.9, 5.5 and 7.2 days for L. muscarium and 4, 5.1 and 6.7 days, for their combination. Results showed significant differences between concentrations; but no two fungi.

COI gene information of medicinal insect *Catharsius molossus*

Cheng-Ye Wang[1], Ying Feng[2]

[1]Chinese Academy of Forestry, China, [2]Chinese Academy of Forestry, China

Catharsius molossus is a commonly used Chinese traditional medicinal insect. After processing, the adults Catharsius molossus usually get broken to pieces and thus get hard to identify. Here we tried to use the DNA barcoding system to identify this medical insect and discriminate it from other morphologically similar segmented bug bodies which might be mixed in. We amplified a 658 bp fragment of the COI gene for 30 individuals of Catharsius molossus collected from different regions in Yunnan Province, southwest of P. R. China. Haplotypes of these individuals differed from each other by no more than five nucleotide substitutions. However, one haplotype differed from others by at least 20 nucleotide substitutions. The large COI sequence difference observed in this individual suggested that some morphologically alike species could likely be mixed in the product of the medicinal insect Catharsius molossus.

Objectives. To determine seasonal dengue infection in Ae. aegypti mosquitoes and dengue infection in suspected patients in 4 central provinces, Thailand. Methods. Ae. aegypti mosquitoes collected twice a season and blood specimens taken from patients with suspected dengue were detected and serotyped for dengue viruses using RT-PCR. The seasonal biting behavior of Ae. aegypti females was studied by mosquito collection once a month as supportive data on dengue infection in the mosquitoes. Results. Dengue infection rates in Ae. aegypti females obtained from all the 4 provinces were highest in hot season and varied from place to place ranging from 64.4 % to 75.5%, whereas morbidity rates of DHF appeared to be highest in rainy season. The occurrence of transovarial transmission was found in local Ae. aegypti larvae and males in all provinces investigated ranging from 18.3 % to 46.9 % and from 12.0% to 46.3%, respectively. Serotyping of dengue virus in Ae. aegypti showed that DENV 3 and DENV 1 were the two most predominant serotypes, followed by DENV 2 and DENV 4. Similarly, DENV 1 and DENV 3 were the two most prevalent serotypes detected in the serum of suspected patients, followed by DENV 2 and DENV 4. The highest biting activity of Ae. aegypti females took place in hot season with the biting rate of 30 mosquitoes/person/hour. Conclusion. Data obtained from this study could be used as powerful tools for virological surveillance in Ae. aegypti populations before the occurrence of dengue outbreaks in endemic and newly dengue-introduced areas.

High throughput transcriptomic analysis to identify *Ixodes ricinus*ticks factors involved in *Bartonella henselae* transmission by ticks

Xiang Ye Liu[1], Martine Cote[2], Muriel Vayssier-Taussat[3], Sarah Irene Bonnet[4]
[1]INRA, France, [2]INRA, France, [3]INRA, France, [4]INRA, France

Bartonella spp. are facultative intracellular bacteria associated with several emerging diseases in humans and animals. Bartonella henselae can cause cat-scratch disease, possibly the most common zoonosis acquired from domestic animals in industrialised countries, and is becoming increasing associated with other syndromes (ocular infections, endocarditic…). We recently reported that Ixodes ricinus is a competent vector both ex vivo for B. henselae and in vivo for Bartonella birtlesii. The aim of the present project is now to investigate the parameters that govern the transmission of the bacteria by tick using the model of B. henselae transmitted by I. ricinus. For that purpose, a functional genomics approach was used to identify the genes that are differentially expressed in ticks in response to infection with B. henselae. Larvae and succeeding nymph ticks were artificially engorged via artificial membrane feeding technique on non-infected or B. henselae-infected blood. Resulting females (87 females for the infected group and 69 for the non-infected one) were then pre-engorged for 4 days in order to stimulate the development of salivary glands. Salivary glands were then dissected and frozen until total RNA extraction. The salivary glands transcriptomes of B. henselae infected and non-infected I. ricinus females were sequenced using high throughput sequencing technologies, and the comparison between the two conditions as well as blast researches were performed. In the present work we report the first results obtained from this analysis. In the future, the role of the differentially expressed genes in the pathogen transmission and development process will be investigated.

VectorMap: Leveraging spatial data on agents of febrile vector-borne infections in support of disease risk assessments

Desmond Foley[1], Richard Wilkerson[2], Lewis S Long[3], Jason Richardson[4], Leopoldo Rueda[5]

[1]Walter Reed Army Institute of Research, U.S.A., [2]Walter Reed Army Institute of Research, U.S.A., [3]Walter Reed Army Institute of Research, U.S.A., [4]Walter Reed Army Institute of Research, U.S.A., [5]Walter Reed Army Institute of Research, U.S.A.

VectorMap (www.vectormap.org) is a web resource for mapping occurrence data and distribution models of agents, primarily arthropods (mosquitoes, ticks, sand flies), involved in febrile vector borne-infections (FVBI). Collection data points, and climate and remote sensing data, are used with ecological niche and other distribution models, to produce predictions of the vector and disease distribution. Disease distribution layers, in an online GIS setting, allow military entomologists and DoD Force Health Protection workers to assess risks worldwide. VectorMap provides critical information on geography/demography, past vector collection data, the possible extent of vector species, and the spatial relationship of vectors to diseases and animal hosts/reservoirs. Mal-area Calculator (MAC) quantifies the overlap of humans, vectors, and disease, in order to estimate vector hazard and FVBI risk for any area of interest. VectorSurv application helps to understand when vector population densities are above average by providing information-rich graphs of species seasonality and abundance. Thus, VectorMap delivers the following: the preservation of valuable data, the display of data in a way that assists infection risk analyses, the promotion of data sharing within AFHSC-GEIS network, and the building of standards and skills.

Feeding efficiency of Odonate species and *Poecilia reticulata* against 3 mosquitoes species in Malaysia

Siti Nurhafizah Saleeza Ramlee
University of Malaya, Malaysia

The use of guppies (Poecilia reticulata) as biocontrol for mosquitoes are well documented but in contrast the use of dragonfly nymphs have been little studied. The efficiency of odonate species, Neurothemis fluctuans, Orthetrum sabina, Orthetrum chrysis and Poecilia reticulate as biocontrol against three common mosquito species in Malaysia, Aedes albopictus, Aedes aegypti and Culex quinquefasciatus larvae were tested under laboratory conditions. The daily feeding rates varied among predators and mosquito species. The mean number of IV instar mosquito larvae consumed by the predators was different between the mosquito species. Aedes aegypti were the most preferred prey for Orthetrum sabina followed by Poecilia reticulata and Neurothemis fluctuans, in the order of 73, 70 and 66 respectively. However, Orthetrum chrysis consumed more Culex quinquefasciatus as a choice prey. Behavior of both mosquito larvae species and predators showed direct influence on the the predatory activities. The feeding rates varied between day time and night time. All predators exhibited diurnal activities being day time stalkers and actively consuming more mosquito larvae during the day compared to night time. The efficiency of predators depended on several factors which are explained in the paper, mainly: escape behavior of prey, search ability and body sizes of predators This study thus lend support to the potential use of odonate species as biocontrol in managing the mosquito species population.

Role of the conserved BBA68-BBA73 operon in the life cycle of Lyme spirochete, *Borrelia bugdorferi*

Xuechao Zhang[1], Haijun Xu[2]

[1]*Zhejiang university, China,* [2]*Zhejiang university, China*

Lyme disease is a global, emerging tick-borne disease caused by the bacterial pathogens of Borrelia burgdorferi s.l. The Lyme spirochete is widely distributed, and hundreds of cases were reported in northeast China each year. In its life cycle, Lyme spirochete dramatically alters the protein profiles when it is transmitted between ticks and mammals. Now, it is proposed that a central signaling pathway, the Rrp2-RpoS pathway, modulates expression of many genes that are vital to mammalian infection. Accumulated data also showed that the BBA68-BBA73 operon partially regulated by Rrp2-RpoS pathway might play a role in this infection process. To elucidate the role of BBA68-BBA73 protein in the enzootic cycle of B.burgdorferi, mutation of bba68 ,bba69 ,bba70 ,bba71and bba73 each gene was generated in an infectious strain of B.burgdorferi by homologous recombination. Groups of C3H/HeJ mice were inoculated intradermally with 106 spirochetes of either wide-type or isogenic mutant spirochete. At 3 weeks after inoculation, mouse tissues (ear, joint, bladder and heart) were collected and cultured in BSK-H medium with 1×Borrelia antibiotic mixture. Our results showed that BBA68, BBA69, BBA71 but not BBA70 and BBA73 are essential for mammalian infection by needle inoculation. The biological role of these proteins in the enzootic cycle of B.burgdorferi employed by tick-mouse model is under investigation.

The first molecular identification of *Borrelia* spp. in *Rhipicephalus sanguineus* (Acari: Ixodidae) from domestic dogs in Taiwan

Chin-Gi Huang[1], Chi-Chun Fang[2], Lu Yun[3], Kun-Hsien Tsai[4], Wen-Jer Wu[5]

[1]National Taiwan University, Taiwan, [2]National Taiwan University, Taiwan, [3]National Taiwan University, Taiwan, [4]National Taiwan University, Taiwan, [5]National Taiwan University, Taiwan

Lyme disease is an emerging tick-borne spirochaetal infection that can lead to multisystem human illness. It is caused by Borrelia burgdorferi sensu lato. Human disease is associated with at least three Borrelia species, B. burgdorferi sensu stricto, B. afzelii, and B. garinii. Recently, the first laboratory-diagnosed human case of Lyme disease caused by B. garinii has been reported in Taipei City in northern Taiwan and B. burgdorferi spirochaetes have been isolated from rodents in the Kimmen County, which is located offshore from the mainland of China. However, the vector species responsible for the transmission of human Lyme disease is still unknown. In this study, brown dog ticks (Rhipicephalus sanguineus) were collected from domestic dogs in the animal hospitals in New Taipei City. The 16S rRNA gene of Borrelia spp. was the target of molecular identification by polymerase chain reaction. Whilst the overall infection rate of Borrelia spp. was 11.25% (16/128), Borrelia spp. were detected in 5 (28%), 2 (11%), 6 (33%) 1 (6%) and 2 (11%) of the samples collected in August, September, October, November, and December in 2011, respectively. Sequences shared 99% homology with both B. burgdorferi and B. garinii. To our knowledge, this is the first report of the Borrelia infection among R. sanguineus in Taiwan. Since parasitism by R. sanguineus amongst humans has become an emerging public health problem, the study of the interactions amongst the Borrelia spp. and R. sanguineus can provide the critical information required for the control and prevention of Lyme disease amongst humans.

Periungual tungiasis and *Rickettsia felis* in cat fleas in the Democratic Republic of Sao Tome and Principe, West Africa

Kun-Hsien Tsai[1], Chi-Tai Fang[2], Chin-Gi Huang[3], Lu Yun[4], Jih-Chin Lien[5], Wen-Jer Wu[6]

[1]National Taiwan University, Taiwan, [2]National Taiwan University, Taiwan, [3]National Taiwan University, Taiwan, [4]National Taiwan University, Taiwan, [5]National Taiwan University, Taiwan, [6]National Taiwan University, Taiwan

A healthy 26-year-old Taiwanese man working in the Democratic Republic of Sao Tome and Principe (DRSTP) in West Africa, presented with a brownish lesion on the medial edge of his right third toe. Examination found multiple eggs of sand flea Tunga penetrans after applying lateral pressure. The lesion contained hindquarters of the dead female sand fleas, which deposit hundreds of eggs in the skin tissues. The infestation usually occurs over unprotected feet. After the excision of the embedded jigger flea from the brownish lesion, he recovered completely. Rickettsia felis is the etiologic agent of flea-borne spotted fever and has been discovered in fleas throughout the world. There have been a few human cases of R. felis infection or data of vector surveillance reported in Africa, including Algeria, Democratic Republic of Congo, Ethiopia, Gabon, Ivory Coast and Tunisia in the last decade. In this study, we describe the first molecular detection of Rickettsia felis in cat fleas (Ctenocephalides felis) in the DRSTP. A total number of 1,092 fleas were collected from domestic dogs in Cantagalo and Agua Grande Province in August 2011. Morphological identification shows these fleas were all Ct. felis. Natural infections of R. felis in cat fleas were isolated and confirmed using polymerase chain reaction. The infection rate in individual flea was found to be 25.11% (57/227). Partial sequences of the citrate synthase, outer membrane protein A, and specific plasmid pRF genes obtained from the samples are 100% identical to those of R. felis URRWXCal2.

New approaches to physical mapping of mosquito genomes

Maria V Sharakhova[1], Vladimir A Timoshevskiy[2], Becky S deBruyn[3], David W Severson[4], Igor V Sharakhov[5]

[1]Virginia Tech, U.S.A., [2]Virginia Tech, U.S.A., [3]Notre Dame University, U.S.A., [4]Notre Dame University, U.S.A., [5]Virginia Tech, U.S.A.

Mosquitoes are vectors of numerous deadly human diseases. To facilitate the development of new strategies for vector control, the genomes of the three most dangerous species of mosquitoes had been sequenced in the last decade. Among these three species, the vector of dengue and yellow fever viruses, Aedes aegypti, has the largest genome with 1,310 Mb, which is hard to assemble and map to chromosomes. Here, we report the first band-based chromosomal map of the Ae. aegypti genome. Idiograms for the mitotic chromosomes of Ae. aegypti were developed. Instead of previously used cell lines, which usually accumulate chromosomal rearrangements, our method utilized chromosomes from a live mosquito. Based on fluorescent in situ hybridization (FISH), a total of 500 BAC clones was assigned to the specific band onto idiograms. From all BAC clones 106 were carrying previously mapped major genetic markers. These BAC clones were additionally ordered within each band by multicolor FISH because of the importance to link their genomic locations to the genetic locations of quantitative trait loci (QTL) related to pathogen transmission. The current study placed ~50% of the Ae. aegypti genome to precise chromosomal positions and also combined cytogenetic, genetic and genome maps into one integrated physical map (iMap) of the yellow fever mosquito. Further application of this map will enhance the quality of the current genome assembly of Ae. aegypti and also will help to find the genomic locations of QTL that might be important targets for developing advanced genome-based strategies for vector/disease control.

Bed bugs are found in many countries around the world and in some regions they are resistant to numerous insecticides. This study surveyed bed bugs in Thailand and determined their resistance to insecticides. The surveys were carried out in six provinces which attract large numbers of foreign tourists: Bangkok, Chonburi, Chiang Mai, Ubon Ratchathani, Phuket and Krabi. Bed bugs were collected from hotels and colonized in the laboratory to evaluate their resistance to insecticides. Cimex hemipterus (F.) was found in some hotels in Bangkok, Chonburi, Phuket and Krabi; whereas, C. lectularius L. was found only in hotels in Chiang Mai. No bed bugs were found in Ubon Ratchathani. The colonized bed bugs showed resistance to groups of insecticides, including organochlorines (DDT, dieldrin), carbamates (bendiocarb, propoxur), organophosphates (malathion, fenitrothion) and pyrethroids (cyfluthrin, deltamethrin, permethrin, lambda-cyhalothrin, etofenprox) in tests using World Health Organization (WHO) insecticide-impregnated papers. The new insecticides imidacloprid (neonicotinoid group), chlorfenapyr (pyrrole group) and fipronil (phenylpyrazole group) were effective against the bed bugs; however, organophosphate (diazinon), carbamates (fenobucarb, propoxur) and pyrethroids (bifenthrin, cypermethrin, esfenvalerate, etofenprox) were ineffective. Aerosols containing various pyrethroid insecticides with 2-4 different active ingredients were effective against the bed bugs. The results obtained from this study suggested that both species of bed bugs in Thailand have developed marked resistance to various groups of insecticides, especially those in the pyrethroid group which are the most common insecticides used for pest control. Therefore, an integrated pest management should be implemented for managing bed bugs in Thailand.

Morphological and molecular phylogenetic studies on a novel anopheline species collected in Kushiro wetland, northern Japan

Nozomi Imanishi[1], Kenji Takai[2], Kyeong Soon Kim[3], Yoshio Tsuda[4], Mutsuo Kobayashi[5], Kyo Itoyama[6], Kyoko Sawabe[7]

[1]Meiji University, Japan, [2]St. Marianna University School of Medicine, Japan, [3]National Institute of Infectious Diseases, Japan, [4]National Institute of Infectious Diseases, Japan, [5]National Institute of Infectious Diseases, Japan, [6]Meiji University, Japan, [7]National Institute of Infectious Diseases, Japan

Since 2004, we have been aware that there exists a population of anopheline mosquitoes in Kushiro wetland, northern Japan, that have a unique DNA sequence different from any of Anopheles sinensis, An. engarensis, An. lesteri and An. sineroides. Based on phylogenetic analysis of internal transcribed spacer 2 (ITS2) sequences of ribosomal DNA, a novel anopheline species was identified to be An. belenrae described from Korea in 2005. Recently we collected An. belenrae mosquitoes in surrounding areas of Kushiro wetland, suggesting a wide distribution of the species in eastern Hokkaido. Phylogeny as well as morphological studies between An. belenrae from Kushiro and other members of Anopheles species inhabiting Japan have never been made. Since An. belenrae inhabiting Kushiro usually has fringe pale spot (Fp) on its wings and is quite similar to An. sinensis and An. engarensis, we conducted more thorough examination to see morphological and phylogenetic differences among An. belenrae and two sibling species, An. sinensis and An. engarensis. Morphological characteristics in adult, pupa and larva were examined and compared. All morphological characteristics examined in this study showed some overlaps among the three species and no definite morphological identification keys were found. Partial ITS2 sequences (491bp) of An. belenrae diverged 14% from both of An. sinensis and An. engarensis. We concluded that An. belenrae inhabiting Kushiro wetland can be well distinguished from An. sinensis and An. engarensis at the DNA level by ITS2 sequences, however no definite morphological identification keys were available at present.

Silkworms in National Bio-Resource Project (NBRP) of Japan

Yutaka Banno[1], Toru Shimada[2], Zenta Kajiura[3], Hideki Sezutsu[4], Hideaki Maekawa[5]

[1]Kyushu University, Japan, [2]University of Tokyo, Japan, [3]Shinshu University, Japan, [4]National Institute of Agrobiological Sciences, Japan, [5]University of the Ryukyus, Japan

National Bio-Resource Project (NBRP) started in 2002 with support by the Ministry of Education, Culture, Sports, Science and Technology Japan. Two research spans (five years each) were already finished and the third season will be started at April, 2012. 28 species including silkworm, medaka (killifish), morning glory, Japanese monkey, arabidopsis and rice are opened for worldwide use. Purpose of NBRP is Collection, Preservation and Distribution of bio-resources that are basic materials for life science researches. Silkworms of NBRP are available by contact to http://www.nbrp.jp/report/reportProject.jsp?project=silkworm. 1.Domesticated silkworm, Mutant strains (500), Improvement strains for artificial diet (200), Transgenic strains (100), 2.Wild silkworm, Antheraea yamamai (5), Antheraea pernyi, Samia cynthia (1), 3. Genomic clones (220,000)(DNA / cDNA) from 50 libraries. When you have some interests for mutants, you can order it every time. Generally, exchange or distribution of eggs is limited in spring season. However, eggs are available during all months by us. For the purpose, we prepare two kinds of eggs in June. One is available for July to early November by the acid-treatment. Another one is available from late November to next April by the artificial hibernation. November is a little bit weak for distribution, but most months are okay to distribute the eggs by this project. For order of the eggs, maternal transfer agreement (MTA) is needed for protection of the property rights of breeder or developer. We try to get foreign country's stocks. We should discuss for the construction of the international organization for information exchanges and network.

Odor-based contagious transmission of pathogen by *Drosophila melanogaster*

kiyoshi okado[1], hirotaka kanuka[2]

[1]*The Jikei University School of Medicine, Japan,* [2]*The Jikei University School of Medicine, Japan*

The housefly and flies are considered to be mechanical vectors of many kinds of pathogens, whereas mosquito serves as the biological vector for pathogens. Mechanical vectors simply convey pathogens and are not essential for their development and life cycle. In order to uncover the molecular mechanisms of transmission by fly, we established a model system for transmission using Drosophila melanogaster. GFP-labeled Escherichia coli located on the center of an agar-plate was freely ingested by Drosophila. Substances excreted in the feces are observed as small spot with fluorescence on the surface of agar, showing that flies directly feed E. coli and disseminate them by excretion. Flies without antennae that contain a large set of olfactory receptors or deficient for Or83b, which encodes a broadly expressed odorant receptor, showed impaired dissemination of bacteria. While wild-type flies showed behavioral responses to attractive odors released from growing E. coli, Or83b mutants failed to respond to these odors. Volatile compounds emitted from culture supernatant of E. coli were trapped and identified by gas chromatography-mass spectrometry (GC-MS). The predominant compound produced by E. coli was indole along with lesser amounts of alcohols. We also showed that LUSH, Drosophila orthologue of indole-binding protein, is required for transmission of E. coli as excreted droplets. Given that Drosophila LUSH is also known as a component to activate pheromone-sensitive neurons, we therefore suggest that the pheromone-mediating system may also promote feeding behavior in the presence of indole from pathogens, contributing to the transmission of infectious diseases such as food poisoning.

Distribution of biting midges *Leptoconops spinosifrons* (Carter) (Diptera: Ceratopogonidae) in Thailand and field efficacy of herbal repellent against *L. spinosifrons*

Usavadee Thavara[1], Apiwat Tawatsin[2], Jakkrawarn Chompoosri[3], Somchai Saengkitporn[4], Preecha Asavadachanukorn[5], Padet Siriyasatien[6], Arunrat Thepparat[7], Mir S. Mulla[8]

[1]Ministry of Public Health, Thailand, [2]Ministry of Public Health, Thailand, [3]Ministry of Public Health, Thailand, [4]Ministry of Public Health, Thailand, [5]Faculty of Commerce and Accountancy, Chulalongkorn University, Thailand, [6]Faculty of Medicine, Chulalongkorn University, Thailand, [7]Faculty of Science, Ramkhamhaeng University, Thailand, [8]University of California, Riverside, U.S.A.

Biting midges Leptoconops spinosifrons (Carter) are annoying pests found on the shorelines and sandy beach areas. In Thailand, L. spinosifrons has been found on various beaches in 9 provinces (Trat, Chantaburi, Rayong, Chonburi, Prachuab Kirikhan, Chumporn, Surat Thani, Nakhon Si Thammarat, Songkhla) around the Gulf of Thailand and 6 provinces (Ranong, Phang Nga, Krabi, Trang, Satun, Phuket) along the Andaman Sea, including some islands located in both seas. The biting midge has two peaks of biting activities (0700-0900 hours and 1600-1800 hours). It feeds on tourists and resident visiting the beaches and resorts. These insects deter human recreation and diminish Thailand tourism. Since the control of biting midges along beaches by larvicides or adulticides is hardly possible, attempts have been made then to prevent its nuisance by using repellent application. An herbal repellent, containing essential oils from Eucalyptus citriodora Hook. and Litsea cubeba (Lour.) Pers., was evaluated for repellency against L. spinosifrons in comparison with N,N-diethyl-3-methylbenzamide (deet). Both repellents were prepared as 20% in ethanol and each one was applied on the clothes (long sleeve T-shirt and pants) at the dosage of 0.5 mg a.i./cm2. Assessments were made using landing rates on the treated clothes as compared with controls (untreated clothes). Both repellents showed relatively high repellency against L. spinosifrons; however, the herbal repellent provided higher degree of repellency (98.3-99.7%) than did deet (82.7-98.5%). This study demonstrates a high potential for use of the herbal repellent to protect from biting of L. spinosifrons.

Keywords:*Biting midge, Leptoconops, Thailand, Repellent*

Comparative detection of chikungunya and dengue virus in *Aedes albopictus* Skuse collected from Surat Thani province, Thailand by multiplex real-time RT-PCR and conventional RT-PCR

Usavadee Thavara[1], Apiwat Tawatsin[2], Jakkrawarn Chompoosri[3], Surapee Anantapreecha[4], Atchara Phumee[5], Veerayuth Kittichai[6], Padet Siriyasatien[7]

[1]Ministry of Public Health, Thailand, [2]Ministry of Public Health, Thailand, [3]Ministry of Public Health, Thailand, [4]Ministry of Public Health, Thailand, [5]Faculty of Medicine, Chulalongkorn University, Thailand, [6]Faculty of Medicine, Chulalongkorn University, Thailand, [7]Faculty of Medicine, Chulalongkorn University, Thailand

This study evaluated two assay methods, multiplex real-time RT-PCR and conventional RT-PCR for detection of chikungunya virus (CHIKV) and dengue virus (DENV) in Aedes albopictus Skuse collected from Surat Thani province, Thailand. The mosquitoes were collected from endemic areas of the province and extracted for viral RNA. The same amount of viral RNA was further processed to detect CHIKV and DENV using the two methods. The positive pools of mosquitoes were determined for chikungunya and each serotype of dengue infection which was used for evaluation of the two methods. One hundred of mosquito pools were assayed for both viruses by both methods. Multiplex real-time RT-PCR could detect CHIKV, DEN-2, and co-infection of DEN-2 and DEN-4 in 24 pools, 9 pools and 1 pool with the infection rate of 24%, 9% and 1%, respectively. In contrast, the conventional RT-PCR found 6 pools positive for CHIKV, with an infection rate of 6% and only DEN-2 was detected in 2 pools with an infection rate of 2%. The chikungunya and dengue positive pools detected by conventional RT-PCR were consistent with those determined by real-time RT-PCR. Real-time RT-PCR assay is more sensitive and reliable than conventional RT-PCR for detection of both viruses in field-caught Ae. albopictus mosquitoes. Since real-time RT-PCR assay provides advantages over conventional RT-PCR, including simple process, easy standardization, rapidity, lower contamination rate and higher sensitivity. It might replace conventional RT-PCR as a powerful tool for rapid detection of viruses in vector mosquitoes and other assayed samples.

Molecular identification of forensically important fresh flies (Diptera: Sarcophigidae) in Thailand by using the second internal transcribed spacer (ITS2) gene

Payu Bhakdeenuan[1], Kanok Preativatanyou [2], Sunchai Payungporn[3], Usavadee Thavara[4], Apiwat Tawatsin[5], Kom Sukontason[6], Kabkaew L. Sukontason[7], Wej Choochote[8], Padet Siriyasatien[9]

[1]Faculty of Medicine, Chulalongkorn University, Thailand, [2]Faculty of Medicine, Chulalongkorn University, Thailand, [3]Faculty of Medicine, Chulalongkorn University, Thailand, [4]Ministry of Public Health, Thailand, [5]Ministry of Public Health, Thailand, [6]Faculty of Medicine, Chiang Mai University, Thailand, [7]Faculty of Medicine, Chiang Mai University, Thailand, [8]Faculty of Medicine, Chiang Mai University, Thailand, [9]Chulalongkorn University, Thailand

In order to determine post mortem interval (PMI) using flies collected from corpses more precisely, accurately identification of flies is essential. Morphology identification of fly especially in the same genus is difficult and required highly expert personals. In this study we evaluate the using of molecular techniques for identification forensically important sarcophigid flies in Thailand using ITS2 gene. A total of 26 specimens of four sarcophigid fly species (Sarcophaga dux, S. ruficornis, S. peregrina and S. scopariiformis) collected from various regions of Thailand were used. When compared sequences with database, the percentage identities range from 99 to 100. Intraspecific variation of each species was 0-0.3%, while the maximum interspecific variation was 19.7%. PCR-RFLP was able to differentiate these four sarcophigid species. The results of this study would be valuable for forensic personnel in order to identify species of forensically importance flies collected from the crime scenes more accuracy and therefore accurate estimate of the PMI.

The bacterial and fungal florai associated with digestive system of *Blattella germanica* L. collected in spring and autumn from dormitories and dwellings in Mashhad, Iran

Gholamhossein Moravvej[1], Mahboobeh Naderi Nasab[2], Sahar Chitsazi[3]

[1]Ferdowsi University of Mashhad, Iran, [2]Mashhad University of Medical Sciences, Iran, [3]Ferdowsi University of Mashhad, Iran

The present study aimed to study the bacterial and fungal flora associated with the digestive system of Blattella germanica L. collected in spring and autumn from dwellings and dormitories in Mashhad, Iran. After dissection of digestive system under sterile condition, the extracts were incubated in EMB and Blood Agar medium. The result showed that in autumn, the most prevalent bacteria in dwellings and dormitories were Klebsiella oxytoca (80%) and Entrobacter aerogenes (96%), respectively. The flora of bacteria associated with dwellings consisted of Enterococcus spp., Staphylococcus spp., Klebsiella spp., Entrobacter aerogenes and Micrococcus spp. All these species except the latter were found in dormitories. Moreover, two species including Proteus vulgaris and P. mirabilis were found in dormitories. The results indicated that 11 out of 50 cockroaches (22%) from houses and 12 (24%) from dormitories were contaminated with fungi. In spring, the most prevalent bacterium in dwellings and dormitories was Enterococcus spp. with the frequencies of 43% and 68%, respectively. The flora of bacteria associated with dwellings consisted of Enterococcus spp., Staphylococcus spp., Klebsiella spp., Entrobacter aerogenes, Serratia marsesens, Proteus spp., Escherichia coli and Tettragen spp. All these species except the latter were found in dormitories. The results indicated that 10 out of 50 cockroaches (20%) from houses and 1 cockroach (2%) from dormitories were contaminated with fungi. The results suggested that for reducing the risk of transmission of various disease agents, suitable control measures should be applied to manage the population of cockroaches.

Chromosomal evolution in *Anopheles* mosquitoes

Ai Xia[1], Maria Sharakhova[2], Scotland Leman[3], Zhijian Tu[4], Igor Sharakhov[5]

[1]Nanjing Agricultural University, China, [2]Virginia Tech, U.S.A., [3]Virginia Tech, U.S.A., [4]Virginia Tech, U.S.A., [5]Virginia Tech, U.S.A.

Anopheles gambiae and An. funestus are primary malaria vectors in Africa, and An. stephensi plays an important role in malaria transmission in Asia. An. gambiae and An. funestus diverged from each other at least 36 million years ago, and An. stephensi is closer related to An. gambiae than to An. funestus. Therefore, these distantly related species are an excellent system for studying the dynamics of chromosomal evolution because inversions are highly nonuniformly distributed among five chromosomal arms. To determine the rates of inversion fixation and better understand the evolutionary forces that govern the unequal distribution of rearrangements among chromosomes, a physical map for A. stephensi, was created and compared with the maps of the major African malaria vectors A. gambiae and A. funestus. The study of paracentric inversions between lineages in Anopheles mosquitoes demonstrated that, despite the paucity of inversion polymorphisms on the X chromosome, this chromosome has the fastest rate of inversion fixations and highest density of transposable elements, simple DNA repeats, and GC content. The highly polymorphic and rapidly evolving autosomal 2R arm has overrepresentation of genes involved in cellular response to stress supporting the role of natural selection in maintaining adaptive polymorphic inversions. In addition, the 2R arm has the highest density of regions involved in segmental duplications that clustered in the breakpoint-rich zone of the arm. In contrast, the slower evolving 2L, 3R, and 3L, arms are enriched with matrix attachment regions that potentially contribute to chromosome stability in the cell nucleus.

Efficacy of lethal ovitraps against *Aedes aegypti* (L.) and *Aedes albopictus* Skuse (Diptera: Culicidae)

Apiwat Tawatsin[1], Usavadee Thavara[2], Jakkrawarn Chompoosri[3], Chayada Khumsawads[4], Nisarat Jonjang[5], Somchai Saengkitporn[6], Preecha Asavadachanukorn[7], Padet Siriyasatien[8]

[1]Ministry of Public Health, Thailand, [2]Ministry of Public Health, Thailand, [3]Ministry of Public Health, Thailand, [4]Ministry of Public Health, Thailand, [5]Ministry of Public Health, Thailand, [6]Ministry of Public Health, Thailand, [7]Chulalongkorn University, Thailand, [8]Chulalongkorn University, Thailand

Ovitraps are artificial breeding containers attracting gravid female mosquitoes to lay eggs and they have been used for surveillance of dengue haemorrhagic fever (DHF) and chikungunya vectors for years; however, these ovitraps could be also modified as tools for integrated vector control. To obtain an effective lethal ovitrap, evaluations of substrate preferences and response of Aedes aegypti (L.) and Ae. albopictus Skuse to ovitraps treated with larvicides were then carried out under laboratory and field conditions. In laboratory, the brown paper substrate showed higher attractiveness for oviposition of both mosquito species than the other candidate substrates (filter paper, sponge sheet and hardboard paddle). Regarding larvicidal comparison, the mean number of eggs laid in ovitraps containing temephos and Bacillus thuringiensis israelensis (Bti) were significantly higher than those laid in ovitraps containing novaluron and untreated ovitraps. No ovicidal effect of the larvicides used in ovitraps was observed since hatching of eggs occurred; however, all larvae died eventually. In field experiments, evaluations of lethal ovitraps having the brown paper as egg-laying substrate treated with temephos compared with the untreated ovitraps were carried out in rubber plantation habitats in Trang province, southern Thailand. There was no significant difference between the mean number of eggs laid in the lethal ovitraps and those laid in the untreated ovitraps. This clearly indicated that no repellent effect was observed in the lethal ovitraps. The lethal ovitrap obtained from this study could possibly be used as an effective, economical and simple mean of DHF and chikungunya vector control.

Insecticidal efficacy of plant extracts against common bed bug *Cimex lectularius* L. (Hemiptera: Cimicidae)

Apiwat Tawatsin[1], Usavadee Thavara[2], Yutthana Phusup[3], Jakkrawarn Chompoosri[4], Somchai Saengkitporn[5], Prapai Wongsinkongman[6], Somchit Niumsakul[7], Nalinphat Saktiyasunthorn[8], Padet Siriyasatien[9]

[1]Ministry of Public Health, Thailand, [2]Ministry of Public Health, Thailand, [3]Ministry of Public Health, Thailand, [4]Ministry of Public Health, Thailand, [5]Ministry of Public Health, Thailand, [6]Ministry of Public Health, Thailand, [7]Ministry of Public Health, Thailand, [8]Ministry of Public Health, Thailand, [9]Chulalongkorn University, Thailand

Bed bugs become serious urban pest in many countries around the world because they are resistant to numerous insecticides commonly used for pest control. Attempts were then made to search for effective and safe materials to control the insecticide-resistant bed bugs. In Thailand, there are numerous plants containing insecticidal effects against various kinds of insects. Extracts from 15 plant species were tested for insecticidal efficacy against Cimex lectularius L. under laboratory conditions. It was found that the fixed oil extracted from Annona squamosa L. and the essential oils extracted from Alpinia galanga (Linn.) Swartz. and Syzygium aromaticum (L.) Merr. & Perry. provided satisfactory insecticidal efficacy against the bed bugs with mortality rate of about 60-80%. These three extracts were then further formulated as oil in water (O/W) emulsion spray and aerosol and tested against bed bugs. Interestingly, the formulated spray and aerosol showed excellent insecticidal efficacy against the bed bugs. The results obtained from this study demonstrated that the plant extracts containing insecticidal effects could be formulated to enhance their efficacies and they could possibly replace synthetic insecticides commonly used for bed bug control.

Metarhizium anisopliae as a potential biopesticide for the brown-banded cockroach, *Supella longipalpa* (Blattaria: Blattellidae)

Yu-Ting Ni[1], Li-Cheng Tang[2]

[1]National Chung Hsing University, Taiwan, [2]National Chung Hsing University, Taiwan

The brown-banded cockroach, Supella longipalpa (F.), is one of the common household pests, while Metarhizium anisopliae (Metschn.) Sorok is an entomopathogenic fungus, safe to human, mammals, and environment. The pathogenicity of M. anisopliae against the brown-banded cockroach was evaluated using three common household pest management techniques i.e., spraying, bait, and pheromone trap. The mortality and LT50 value were 78.3% and 9.8 days, respectively, when S. longipalpa was sprayed directly with a M. anisopliae suspension at 1.6×10^8 conidia/ml. The suspension was sprayed on the surface of different materials commonly used for interior decoration in which those with smoother surface caused higher mortality; for example, plastic > tile > glass > stainless sheet steel > wood, when applied at 1.6×10^9 conidia/ml. The bait was prepared by combining the preferred food of the cockroach with the M. anisopliae conidia. Its fecal extracts extracted with methanol or methylene chloride were able to enhance fungal infection and the bait performance. The trap containing methanol fecal extracts increased 22.0% of the capture rate compared with the control group. Our assays using a ratio of 1:10 (exposed : unexposed to conidia) resulted in 30.0% mortality in healthy colonies, indicating that M. anisopliae can be transmitted horizontally within S. longipalpa populations. Therefore, M. anisopliae could be a potential biopesticide for managing this cockroach when applied alone or in combination with food baits or with the bait stations containing fecal extracts.

Breeding sites of main Bluetongue virus vectors in Belgian cowshed

Jean-Yves Zimmer[1], Claude Saegerman[2], Bertrand Losson[3], Eric Haubruge[4], Frederic Francis[5]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege, Belgium, [3]University of Liege, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium

Bluetongue (BT) is an emerging vectorborne disease of ruminants that was reported in August 2006 in northern Europe. Since 2007, BT virus (BTV) serotype 8 continued its spread across Europe and caused considerable economic losses. This observation indicates possible overwintering of the vector from year to year. The biological vectors of BTV are biting midges of the genus Culicoides. Breeding sites of bluetongue vector species have been found near farms (e.g. silage residues) and in neighboring meadows (e.g. cattle dung) but never inside sheds. We conducted a study in five cattle farms in Belgium during February?October 2008. Three samplings were performed and each soil sample collected inside cowsheds was incubated to enable adult midges to emerge. Among 15 soil biotopes sampled, only one showed the emergence of adult Culicoides biting midges: dried dung adhering to walls inside animal enclosures and resulting to the partial removal of used animal litter. It was a breeding site for the C. obsoletus/scoticus complex. Physico-chemical characteristics showed that midges of this complex are more prevalent in soil samples with a high carbon:nitrogen (C:N) index. So Culicoides biting midges are able to complete their life cycle in animal enclosures. We identified a breeding site for the primary BTV vector in a cowshed in northern Europe. These observations could explain the persistence of BTV from year to year despite fairly harsh winters. Hygienic measures on farms could reduce biting midges populations and so improve efficacy of vaccination campaigns against BT in Europe.

Laboratory evaluation of efficacy of *Bacillus thuringiensis* Crude toxin (Bt.Ct) and Bt.Ct synthesized silver nanoparticles (Bt.Ct-AgNps) against human vector mosquitoes

Asanmoohamed Najitha banu[1], Chelliah Balasubramanian[2], Puthamohan Vinayaga Moorthi[3], Thangavel kubendran[4]

[1]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India, [2]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India, [3]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India, [4]Thiagarajar College (Autonomous), Tepakkulam, Madurai-09, Tamil Nadu, India

A comparative study was carried out under laboratory condition using Bt.Ct and Bt.Ct-AgNps against Aedes aegypti, Culex quinquefasciatus and Anopheles stephensi. Bt.Ct synthesized AgNps was characterized and conformed using UV-vis spectra, SEM and EDX. The bioassay study using Bt.Ct revaled the present cumulative mortality of 97.8%, 90% and 93.33% with respect to A. aegypti, Cx. Quinquefasciatus and An. stephensi thus, tested bacterial strain would be a potent larvicide against Human vector mosquitoes and can also be recommended for the field evaluation.

A long-term pattern of prevalence of dragged ticks captured in the Korean Peninsula from 2001 to 2010

Baek Jun Kim[1], Sungjin Ko[2], Jun-gu Kang[3], Heung Chul Kim[4], Sung Tae Chong[5], Terry A. Klein[6], Joon-Seok Chae[7]

[1]College of Veterinary Medicine, Seoul National University, Republic of Korea, [2]College of Veterinary Medicine, Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]168th Multifunctional Medical Battalion, 65th Medical Brigade, Unit 15247, Republic of Korea, [5]168th Multifunctional Medical Battalion, 65th Medical Brigade, Unit 15247, Republic of Korea, [6]Seoul National University, U.S.A., [7]Seoul National University, Republic of Korea

Many infectious diseases of humans have been increasingly emerged as zoonoses transmitted by vectors. Vector-borne diseases are a major contributor to the global health burden in the world. Among the vectors, tick-borne diseases have risen dramatically over the last two decades. Here, a long-term prevalence of Korean tick-borne diseases was shown together with information of Korean tick species. Samplings of ticks were carried out during the last ten years (2001-2010) and ten infectious agents were screened in this study. A total of 16,375 ticks were collected from the wild habitats by dragging. Based on the results, seven tick species belonging to three genera (Haemaphysalis, Ixodes and Amblyomma) were found from seven provinces during the study period. Except unidentified ticks, H. longicornis (n=8828; 53.91%) was the most frequently sampled tick, followed by H. flava (n=5593; 34.16%), I. nipponensis (n=753; 4.49%), I. turdus (n=21; 0.13%), A. testudinarium (n=20; 0.12%), H. Japonica (n=12; 0.07%) and I. persulcatus (n=8; 0.05%). Larvae (n=7858; 47.99%) and nymphs (n=7597; 46.39%) of Haemaphysalis spp. and Ixodes spp. were sampled most frequently but only nineteen nymphs and one male adult of A. testudinarium were sampled by dragging. In addition, from 2001 to 2009, various infectious agents were detected with a unique Minimum Field Infection Rate (MFIR). Among them, Rickettsia spp. showed the highest MFIR (6.29%), followed by Bartonella spp. (1.67%), Ehrlichia chaffeensis (1.42%), Borrelia burgdorferi (1.33%) and Anaplasma platys (1.26%). This long-term monitoring of dragged ticks would be helpful to understanding the distribution of ticks, abundance and infection.

The IR3535 derivative (LJH158), in which the ethyl ester of IR3535 was converted to the methyl ester, was synthesized and studied as the new mosquito repellent ingredient. The repellent efficacy of LJH158 was compared with that of DEET against Aedes albopictus, Culex pipiens pallens and Aedes togoi. Also, the aromatic repellent tests were conducted with the mixtures of repellents and the essential oils of cinnamon which were obtained by supercritical extraction. In addition, the safety issues of LJH158 were monitored through single oral dose safety study, eye irritation test, and skin irritation test. The results of repellent efficacy in both biting and aromatic tests and safety tests suggest that LJH158 has high potential to be used as a new repellent ingredient.

Keywords:*mosquito, repellent, IR3535, LJH158, Cinnamon, supercritical extraction*

Influence of antimicrobial peptides over-expressed in damaged gut cells of *Drosophila melanogaster*

Eun-Young Yun[1], Young-Il Yoon[2], Jae-Sam Hwang[3], Tae-Won Goo[4], Eun-Young Kwon[5], Jeongmi Yoo[6]

[1]National Academy of Agricultural Science, Republic of Korea, [2]National Academy of Agricultural Science, Republic of Korea, [3]National Academy of Agricultural Science, Republic of Korea, [4]National Academy of Agricultural Science, Republic of Korea, [5]National Academy of Agricultural Science, Republic of Korea, [6]National Academy of Agricultural Science, Republic of Korea

To investigate the cause of Inflammatory bowel disease (IBD) by using Drosophila melanogaster, we created a D. melanogaster intestinal damage model by orally feeding the flies with various IBD inducers. After feeding the flies with IBD inducers of LD50, we found that in the damaged gut cells, the number of enteroendocrine cells secreting antimicrobial peptides (AMPs) had increased and the expression level of the AMPs, and upstream signalling of the AMPs (Toll, Pelle, Dorsal and Relish) had up-regulated. We also confirmed that apoptosis and intestinal stem cells (ISCs) had markedly increased in the damaged gut cells. On the other hand, results obtained by using RNA interference (RNAi) lines for the knockdown of various AMP genes showed that the survival rate had increased and apoptosis had decreased in the RNAi lines as compared to wild-type flies. Anti-Toll, anti-Dorsal, and anti-Pelle antibody feeding flies survived longer than normal flies after feeding with DSS. We deduce from the above results that when IBD inducers entered the fly gut, various AMPs were up-regulated for self-defense. Over-expressed AMPs not only function in intestinal protection by destroying harmful microorganisms, but also function in intestinal destruction by attacking their own cellular components. Hence, we suggest that AMPs that are over-expressed by IBD inducer could be a possible cause of IBD.

Allergenicity of recombinat alpha-amylase from German cockroach

Kyoung Yong Jeong[1], Jung-Won Park[2], Tai-Soon Yong[3]

[1]Yonsei University College of Medicine, Republic of Korea, [2]Yonsei University College of Medicine, Republic of Korea, [3]Yonsei University College of Medicine, Republic of Korea

Cockroach produces potent allergens. Especially, feces are known to be rich in allergens. By the analysis of German cockroach fecal extract, α-amylase was found to be allergenic. German cockroach α-amylase shared the highest identity with pig α-amylase (56.5%), followed by mite group 4 allergens (Blo t 4, 50.6%; Der p 4, 50.0%; Eur m 4, 47.6%). In this sduty, recombinant α-amylase from German cockroach was expressed and its allergenicity was examined by ELISA. Specific IgE against recombinant amylase was detected from 40 % (12/30) of serum samples from German cockroach-sensitized subjects. Amylase is found to be one of the important allergen in cockroach feces. It is hoped that recombinant amylase will be useful for further studies and clinical applications.

Carbamate insecticides bioassays and resistance monitoring in field strains of adult German cockroach, *Blattella germanica* (L.), from southern Iran

Mohammad Reza Fakoorziba[1], Mohammad Djaefar Moemenbellah-Fard[2], Mohsen Mohebbi-Nodezh[3], Kourosh Azizi[4]

[1]School Of Health and Nutrition, Shiraz University of Medical sciences, Iran, [2]School Of Health and Nutrition, Shiraz University of Medical Sciences, Iran, [3]School Of Health and Nutrition, Shiraz University of Medical sciences, Iran, [4]School Of Health and Nutrition, Shiraz University of Medical sciences, Iran

The German cockroach, Blattella germanica L. (Dictyoptera: Blattellidae), has become resistant to many insecticides due to control failures. This study was designed to detect and monitor carbamate resistance in field strains of German cockroach by using lethal dose bioassay methods. Two wild German cockroach strains (dormitory 'D' and hospital 'H') were collected. Adult males were subjected to the jar exposure procedure. A range of concentrations starting with WHO standard concentration of carbamate insecticides (carbaryl, bendiocarb, propoxur) were used in a jar bioassay format. For each, four to seven different concentrations leading to >0% and <100% mortality were used. Ten cockroaches were placed in each jar and the exposure time of contact was held constant for 30 minutes. Mortality data and slopes from the replicates were assessed using probit analysis. Although both strains showed lethality values above those of the WHO standards, the 'H' strain was more resistant to all of the three carbamate insecticides than the 'D' strain. The order of resistance for 'D' strain was carbaryl> propoxur > bendiocarb, while the order of resistance for 'H' strain was carbaryl> bendiocarb > propoxur. The ratio of LD50 in 'H' strain to that of 'D' strain for carbaryl was about twice that of the other two insecticides. It is concluded that heavy reliance on carbaryl in both 'D' and 'H' settings has led to resistance and control failures. A set of basic rotations with mosaics of different classes of insecticides may be used in future.

Scabies disease prevalence and social factors affecting referrals to health centers in Hamadan and Kermanshah provinces during the years 2006 -2011

Mansour Nazari

Hamadan University of Medical Sciences, Hamadan, Iran

Scabies, a parasitic skin infestation by the burrowing "itch" mite Sarcoptes scabiei, causes significant health problems for children and adults worldwide. Due to the lack of information about scabies disease in the west of Iran and the numerous reports of this disease, this study was to clarify the disease status. This investigation is a descriptive, cross sectional study. The disease was diagnosed based on clinical examination and microscopic observation of the parasite in the ulcer site from March 2006 to March 2011 referrals to health centers in Hamadan and Kermanshah provinces. The prevalence of scabies in Hamadan and Kermanshah provinces referred to health centers were determined approximately 0.0005. All cases of scabies in Hamadan and Kermanshah provinces is 177 peoples, that 170 (96%) of Kermanshah Province, and 7 patients (4%) is in Hamadan province. 73 (41.2%) of patients were illiterate and 104 (58.8%) had primary education or higher. 26 patients (14.7%) to 4 persons in households, and 151 (85.3%) in households of 5 persons or more are diagnosed with the disease. 104 (58.7%) of patients in the near or far from the place of residence had domestic animals, and 73 (41.3%) had no livestock. The housing situation of people with gall disease in 100 patients (56.5%) had inadequate housing, 75 (42.4%) with proper brick houses and 2 patients (1.1%) had a shed. Health education (personal hygiene and daily cleaning) and identifies those infected (quarantine and treatment) to reduce contamination to be removed from this disease is an important step.

Abundance and dominance of sand fly species (Diptera: Psychodidae: Phlebotominae) in Zahedan County, Sistan - Baluchistan Province, Southeastern Iran

Hamid Kassiri[1], Ezat-Aldin Javadian[2]

[1]Ahwaz Jindishapur University of Medical sciences, Iran, [2]Tehran University of Medical sciences, Iran

Phlebotomine sand flies are the vectors of various types of leishmaniasis in Iran . In order to understand the faunal composition of sand flies , this survey was done in Zahedan county . A total of 13 cities an villages were screened for sand flies . Collections were made in 1997 ? 1998 . The specimens were collected by sticky paper traps coated with castor oil . The specimens collected were preserved in alcohol and slides were prepared in Puri's medium . In this study 6323 specimens were collected . We found nine species of Phlebotomus and thirteen species of Sergentomyia . P . papatasi (23.5%) , S . tiberiadis (17.7%) , S . clydei (14.2%) , S . sintoni (12.9%) , P . sergenti (9.1%) , P . alexandri (7.9%) and P . kazeruni (6.7%) were the predominant Phlebotomine species in our investigation . During the collection of sand flies , the species of , P . bergeroti , P . halepensis , P . keshishiani , P . major , S . africana , S . baghdadis , S . clydei , S . dentata , S . dreyfussi , S . grekovi , S . hodgsoni , S . iranica and S . sumbarica were collected for the first time from this county. In this study P . papatasi had highest density in Zahedan county . High density of P . papatasi and P . sergenti in this district could indicate risk of spread cutaneous Leishmaniasis.

Cockroaches [*Periplaneta americana* (L.), Dictyoptera; Blattidae] as carriers of bacterial pathogens, Khorramshahr County, Southwestern Iran

Hamid Kassiri[1], Shahnaz Kazemi[2]

[1]*Ahwaz Jindishapur University of Medical sciences, Iran,* [2]*Khorramshaher Health Center, Iran*

American cockroaches are found in association with human dwellings and hospitals. They have a worldwide distribution. These domestic pests affect human health in several ways. Their habits make them ideal mechanical carriers of different pathogenic microorganisms. Numerous bacteria of medical importance have been isolated from cockroaches. The objective of this research was to determine the role of American cockroaches as carriers of pathogenic bacteria. This was accomplished through the isolation and identification of these microorganisms from the external surfaces of cockroaches captured in Health and Medical Services Centers and their surroundings. Seventy-three cockroaches were caught in Health and Medical Services Centers in Khorramshahr County, southwestern Iran, in 2006. The fluid used to wash the external surfaces of cockroaches was cultured to isolate and identify bacterial pathogens. Pathogenic bacteria were isolated from the external surfaces of 100% of the American cockroaches examined. The following bacterial pathogens were recovered from their body surface:Klebsiella (47.9%), Pseudomonas (37%), Escherichia coli (30.1%), Staphylococcus (24.6%), Enterobacter (19.2%), Streptococcus (15.1%), Serratia (8.2%), Bacillus (4.1%), and Proteus (2.7%). The bacterial pathogenic flora isolated from this cockroach species indicate that domestic pests could pose a health problem to humans. Thus, we must control cockroaches, particularly in indoors, sewage and solid wastes .

Data on sand fly fauna (Diptera, Psychodidae, Phlebotominae) in Khash County, Sistan - Baluchistan Province, Southeastern Iran

Hamid Kassiri[1], Ezat-Aldin Javadian[2]

[1]*Ahwaz Jindishapur University of Medical sciences, Iran,* [2]*Tehran University of Medical sciences, Iran*

Sand flies are the biological vectors of leishmaniasis all around the word. In 1997, sand flies were collected in 14 cities and villages of Khash County, using 848 sticky traps. A total of 4,673 sand flies were collected mainly from mountainous areas.The following 21 species were found : Sergentomyia tiberiadis (23.6%) , Phlebotomus kazeruni (24.4%) , P . sergenti (18.1%) , P . alexandri (12.9%) , P . papatasi (6.1%) , S .sintoni (4.9%), S . hodgsoni (3.9%) , S . baghdadis (1.7%) , S . dentate (1.2%) , S . mervynae (1.1%) , S . clydei (1%) , S . christophersi (0.3%) , P . eleanorae (0.2%) , S . dreyfussi (0.1%) , P . bergeroti (0.1%) , P . halepensis (0.08%) , S . iranica (0.06%) , S.theodori (0.06) , S . africana (0.04%) , P . major (0.04%) and P . mesghali (0.02%) . The following 14 species were reported for the first time from Khash County: P. papatasi, P .bergeroti, P. eleanorae, P. halepensis, P. major, P. mesghali, S. hodgsoni, S. mervynae, S. dreyfussi, S. iranica, S. theodori, S. africana, S. clydei and S. christophersi. The composition of species in Khash county is almost similar to the other parts of Iran. However, the dominance of P. kazeruni in Khash County may suggest that this species should be considered as a potential vector in the region of Khash.

American cockroaches [*Periplaneta americana* (L.), Dictyoptera, Blattidae) as potential vectors of nosocomial infections, Ahwaz City, Khuzistan Province, Southwestern Iran

Hamid Kassiri[1], Mohammad-Reza Sepand[2]

[1]*Ahwaz Jindishapur University of Medical sciences, Iran,* [2]*Ahwaz Jindishapur University of Medical sciences, Iran*

American cockroaches act as a main mechanical vector for many pathogenic bacteria . These agents can stay alive for a few days on external parts of cockroach's body . The aim of this research was to confirm that P . americana carry pathogenic bacteria in some hospitals. Fifteen cockroaches were catched from different wards of three hospitals (namely Arya , Sina and Amir ? Almohmenin) of Ahwaz city using direct collection , during 2006 . Collected cockroaches were identified according to systematic keys . The washing fluid from external surface of cockroaches were cultured for identify bacteria according to standard microbiological procedures . Results of culture media showed that 100% of cockroaches were positive to the bacteria . Among three hospitals it is found that Sina hospital was more infected . All the American cockroaches were infected to at least one bacterium . The main common bacteria was found Escherichia coli at which 86.7% of cockroaches were infected . The second common diagnosed bacterium was found to be Proteus vulgaris at which 73.3% external infection by this bacterium was reported . The least contamination was approved to Staphylococcus vulgaris . Only 6.7% of cockroaches were externally infected . In addition to these bacteria , Bacillus cereus (66.7%) , Streptococcus faecalis (60%) , Staphylococcus aureus (60%) , Enterobacter cloacae (53.3%) , Shingella (33.3%) and Serratia (13.3%) were isolated on cockroaches . Results exhibited that the presence of American cockroaches in the hospitals can threaten the health of hospitalized patients.

A survey on species of isolated bacterial agents from american cockroaches (*Periplaneta americana*) in residential areas of Ahwaz City, Khuzistan Province, Southwestern Iran

Hamid Kassiri[1], Anvar Ghaderi[2], Mahmod-Reza Shiravand[3]

[1]Ahwaz Jindishapur University of Medical sciences, Iran, [2]Ahwaz Jindishapur University of Medical sciences, Iran, [3]Ahwaz Jindishapur University of Medical sciences, Iran

American cockroaches are often found in close association with humans, living in human places . Because of their association with human dewellings, cockroaches may incidentally contact and acquire human pathogens. The aim of this descriptive laboratory study was to assess the role of American cockroaches as potential carriers of pathogenic bacteria. This study was conducted in 2008 . A total of 25 American cockroaches were collected using hand catch method from houses. The cockroaches were transferred to clean tubes. Samples were transported to the laboratory. Then the cockroaches killed and identified. Bacteria on the body of cockroaches were isolated and identified with using the standard isolation techniques. Different species of bacteria were associated with cockroach. The bacteria showed various cultural, morphological and biochemical features. Medically important bacteria were isolated from external surface of 100% of cockroaches . Eleven bacterial species were isolated from cockroaches. The most common detected bacteria were found to be Escherichia, Staphylococcus aureus, Proteus, Klebsiella, Citrobacter and Enterobacter at which 100%, 72%, 60%, 60%, 56% and 52% of cockroaches were infected, respectively. The finding of E.coli among cockroaches means that these insects have been in contact with human faeces or faeces contaminated tools. The minimum contamination was approved to Serratia (20%), Micrococcus (32%) and Enterococcus (40%). The other extracted bacteria in this research were Psudomonas (44%) and Sterptococcus (48%) It is necessary to control these insects for providing a clean and healthy place. Application of low risk pesticide will reduce the harmful health effect of cockroaches .

An epidemiological study of *Pediculus capitis* infestation in the Cases of Attending to the Azna Health Centers, Lorestan Province,Western Iran

Hamid Kassiri[1], Hamid Amani[2]

[1]*Ahwaz Jindishapur University of Medical sciences, Iran,* [2]*Azna Health Services Center, Iran*

Head louse, Pediculus capitis, is an obligatory ectoparasite with a worldwide distribution. This descriptive study was conducted on the cases with head lice infestations that attended to the Azna Health Centers and were examined by the trained health staff, during 2007. Suspected hairs of head were examined for nits and lice. Epidemiologic information of patients were recorded and collected in the questionnaires. Recorded data in the questionnaires were analyzed by SPSS software. The infestation of head lice was 95 cases . All infested cases were found among the females. The incidence of pediculosis was greater in the villages (70.5%) than in the urban (29.5%) areas. The prevalence rate of pediculosis among the age groups of <6, 6-10, 11-17 and >17 years old were 10.5% , 62.1% , 24.2% and 3.2%, respectively. Eighteen cases (18.9%) of patients had infestation background to pediculosis and 77 cases (81.1%) were without infestation background. The frequency of nit infestation was 90 cases and with adult and nymph were five cases. Remarkable percentage of patients (78%) complained from head itching. Seventy cases of patients were observed among the people who have used of common tools such as combs and towels. Most of the patients (79%) were without healthy bathroom at home. About 75.8% of patients had elementary knowledge. As the data of this study showed, head louse is an important health problem in Azna county, especially among the people with low education, who live in the area with poverty, low health and overcrowded conditions.

Epidemiological and clinical characteristics of scorpion sting in Bagh-e-Malek County, Khuzistan province, Southwestern Iran

Hamid Kassiri[1], Ali Teimori[2]

[1]Ahwaz Jindishapur University of Medical sciences, Iran, [2]Izeh Health Services Center, Iran

Forty to fifty thousands of scorpion sting cases and at least 7-60 death cases are reported annually from Iran. Around 25000 sting cases and several death cases are reported annually from Khuzistan province, where Hemiscorpius lepturus sting is responsible for 95% of stings. According to scorpionism importance in Bagh-e-Malek County, this cross sectional - descriptive study was conducted in 2007-2008 . Required informations were drawn from patient's files and reported in a questionnaire that was prepared for this purpose. After coding, the data were analyzed by spss software. This study was conducted on 524 victims . Totally, 363 (69.3%) patients were living in rural areas. 302 (57.6%) of sting cases were among women The most cases were belonging to age groups of 15-24 and 25-34 years old with 28.4% and 23.8% abundance, respectively.The most sting cases have occured in summer (46.8%) . Nearly, 214 patients (40.8%) were stung on the hand and 210 (40.1%) on the foot. The highest (77.2%) stings have occured at night . 45.4% of studied cases were stung at 0-6 . About 83% of patients were stung in indoors. The most prevalent symptoms of scorpionism were: pain of sting place (72.7%), irritation and wound (15.6%), severe muscle pain (7.8%) and numbness of sting place (3.9%). Patient's care, faster use of antivenum in emergency cases and recommended to be relax can be very effective in saving lives. Provide the necessary training for the families about safety principals observance is very useful to decrease the scorpion sting.

Insecticidal activity of *Moringa oleifera* seed extract against a dengue vector, *Aedes aegypti* L. (Diptera: Culicidae) in Faisalabad, Pakistan

Muhammad Ashfaq[1], Waqas Wakil[2], Umair Ashfaq[3]

[1]University of Agriculture Faisalabad, Pakistan, [2]University of Agriculture Faisalabad, Pakistan, [3]Government College University, Faisalabad, Pakistan

The larvicidal, pupicidal and repellent effect of the water extract of Moringa oleifera seeds was assessed against the dengue vector Aedes aegypti L. (Diptera: Culicidae). The bioassays were conducted under laboratory and in field conditions. Larvicidal effect of the treatments was assessed at different concentrations (0, 25, 50, 75 and 100 mg/L) after 12, 24, 36 and 48 h of the exposure against 2nd and 4th instar larvae, following the procedure of WHO with some modifications. The pupicidal activity was checked at same dose rates after 48 h of the treatments. The repellent activity of the extract was performed with human volunteers and dose-response method was used to estimate the percentage protection. The potential breeding habitats of the endemic areas of the district were sprayed and effect was recorded as percentage reduction in larval density. The results indicated significant effect of the treatments and the effectiveness increased with extended exposure interval with enhanced dose rates. The findings of the present study clearly revealed that water extract of M. oleifera seeds is an effective agent for the control of Ae. aegypti at its larval and pupal stage and exhibits good repellent action against adults, however, the efficacy depends upon dose rates and the exposure interval.

Contact and fumigant toxicity of *Pinus densiflora* needle hydrodistillate constituents and related compounds and efficacy of spray formulations containing the oil to *Dermatophagoides farinae*

Ju-Hee Lee[1], Jun-Ran Kim[2], Young Yull Koh[3], Young-Joon Ahn[4]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]Seoul National University, Republic of Korea

The toxicity of red pine needle hydrodistillate (RPN-HD), 19 RPN-HD constituents and 12 structurally related compounds and control efficacy of four experimental spray formulations containing RPN-HD (0.5, 1, 2 and 3% sprays) to adult Dermatophagoidesfarinaewas evaluated. RPN-HD (24 h LC50,68.33 µg cm^2) was toxic. Menthol was the most toxic compound (12.69 µg cm^2) and the toxicity of this compound and benzyl benzoate did not differ significantly from each other. High toxicity was also produced by α-terpineol, bornyl acetate, geranyl acetate, thymol, linalyl acetate, terpinyl acetate, citral, linalool and camphor (18.79?36.51 µg cm^2). These compounds were more toxic than either deet or dibutyl phthalate. In vapour-phase mortality tests, these compounds were consistently more toxic in closed versus open containers, indicating that their mode of delivery was largely a result of vapour action. RPN-HD 3% experimental spray provided 95% mortality against adult D. farinae, whereas permethrin (cis:trans,25:75)2.5gL^-1 spray treatment resulted in 0% mortality. In the light of global efforts to reduce the level of highly toxic synthetic acaricides in indoor environments, RPN-HD and the compounds described merit further study as potential biocides for the control of Dermatophagoides populations as fumigants with contact action.

Fumigant toxicity of plant essential oils against camptomyia corticalis (Diptera: Cecidomyiidae)

Jun-Ran Kim[1], Perumalsamy Haribalan[2], Bong-Ki Son[3], Young-Joon Ahn[4]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]Seoul National University, Republic of Korea

The toxicity of 102 plant essential oils against third instars of cecidomyiid gall midge, Camptomyia corticalis, was examined using a vapor-phase mortality bioassay. Results were compared with that of a conventional insecticide dichlorvos. Based on 24 h LC50 values, all essential oils were less toxic than dichlorvos (LC50, 0.027 mg/cm^3). The LC50 of caraway seed, armoise, sage (Clary), oreganum, lemongrass, niaouli, spearmint, cassia special, sage (Dalmatian), thyme red, bay, garlic, and pennyroyal essential oil is between 0.55-0.60 mg/cm^3. The LC50 of cassia pure, thyme white, cassia redistilled, star anise, peppermint, wintergreen, cinnamon bark, majoram, chamomile romon, eucalyptus, rosemary, cedar wood, pimento berry, savory (summer), lavender, and coriander oil is between 0.61-0.99 mg/cm^3. All other essential oils tested exhibited low toxicity to the cecidomyiid larvae (LC50,>0.99 mg/cm^3). The active principles of active essential oils were identified by GC-MS analysis. The major active principles are such as pulegone, thujone, camphor, 1,8-cineole, a-pinene, thymol, menthol. At a rate of 5 mg/cm^3, pulegone, and thujone, exhibited 100% morality whereas camphor, 1,8-cineole, α-pinene, thymol and menthol showed 90% mortality at 15 mg/cm^3. Global efforts to reduce the level of highly toxic synthetic insecticides in the agricultural environment justify further studies on the essential oils and their constituents described as potential insecticides for the control of the mushroom fly as fumigants with contact action.

Transovarial transmission of *Orientia tsutsugamushi* in *Leptotrombidium palpale* (Acari: Trombiculidae)

Eun Hee Shin[1], Jong Yul Roh[2], Won Il Park[3], Bong Gu Song[4], Chan Park[5], Mi-Yeoun Park[6], E-hyun Shin[7]

[1]Korea National Institute of Health, KCDC, Republic of Korea, [2]Korea National Institute of Health, KCDC, Republic of Korea, [3]Korea National Institute of Health, KCDC, Republic of Korea, [4]Korea National Institute of Health, KCDC, Republic of Korea, [5]Korea National Institute of Health, KCDC, Republic of Korea, [6]Korea National Institute of Health, KCDC, Republic of Korea, [7]Korea National Institute of Health, KCDC, Republic of Korea

Tsutsugamuhi disease is transmitted through biting by unfed larval trombiculid mites infected with Orentia tsutsugamushi (Hayashi). It is a notorious vector borne disease in Korea. There were more than 5,000 cases annually since 2004. Leptotrombidium palpale was one of the vector mites of Tsutsugamushi disease in Korea. Transovarial transmission of O. tsutsugamushi was studied in two generations (P, F1) of naturally-infected L. palpale. When compared with uninfected mites, the naturally-infected L. palaple showed no significant difference in the oviposition rate but higher hatching rate. The uninfected female produced only uninfected progenies in both cases of mating with either an infected or uninfected male. However, the infected female vertically transmitted O. tsutsugamushi to its progenies in both case. The transovarial infection rates of parental and F1 generation was 100%. The overall filial infection rate in F1 generation was 100%, but this rate was declined to 95.3% in F2. This high rate of transmvarial transmission suggests that L. palpale might be one of major vector of tsutsugamushi disease in Korea.

Keywords:*trombiculid mite, transovarial transmission, scrub typhus*

Seasonal distribution of chigger mites surveillance using new chigger mite collecting traps in Korea (2010~2011)

Won Il Park[1], Jong Yul Roh[2], Eun Hee Shin[3], Bong Gu Song[4], Chan Park[5], Mi-Yeoun Park[6], Jin Suk Han[7], Hyeon Joo Lee[8], E-hyun Shin[9]

[1]Korea National institute of Health KCDC, Republic of Korea, [2]Korea National institute of Health KCDC, Republic of Korea, [3]Korea National institute of Health KCDC, Republic of Korea, [4]Korea National institute of Health KCDC, Republic of Korea, [5]Korea National institute of Health KCDC, Republic of Korea, [6]Korea National institute of Health KCDC, Republic of Korea, [7]Goryeong-gun, Gyeongsangbuk-do, Republic of Korea, [8]Hwaseong-si, Gyeonggi-do, Republic of Korea, [9]Korea National institute of Health KCDC, Republic of Korea

A surveillance of chigger mites was conducted to clarify the seasonal distribution of scrub typhus vectors by new chigger mite collecting traps from each 4 collection points of 2 regions from 2010 to 2011 in Korea. During the surveillance period, the population density of chigger mites had two peaks, one big peak in October-November and another small peak in March. In Hwaseong-city, a total of 185 mites representing 3 genera and 5 species were collected and the predominant species were Leptotrombidium pallidum (46.5%) and L. palpale (36.2%). In Goryeong-gun, a total of 1,397 mites representing 3 genera and 8 species were collected and the predominant species were L. scutellare (54.8%), L. pallidum (20.0%) and L. palpale (18.6%). The high collecting rates were recorded at field (92.8%) and at rice field (43.2%) in Hwaseong-city and Goryeong-gun, respectively. This result show that the surveillance of scrub typhus vectors by new chigger mite collecting trap is useful as an alternative for a conventional method by trapping wild rodents. but further research on increasing collection rate will be needed.

Insecticide resistance monitoring in the principal Japanese encephalitis vector, *Culex tritaeniorhynchus* using bioassay and biochemical assays

Hyun Kyung Kim[1], Dae Hyun Yoo[2], Seong Yoon Kim[3], E Hyun Shin[4], Mi Yeoun Park[5], Kyu Sik Chang[6], Young Joon Ahn[7], Dong-Kyu Lee[8]

[1]Korea Center for Disease Control & Prevention, Republic of Korea, [2]Korea Center for Disease Control & Prevention, Republic of Korea, [3]Korea Center for Disease Control & Prevention, Republic of Korea, [4]Korea Center for Disease Control & Prevention, Republic of Korea, [5]Korea Center for Disease Control & Prevention, Republic of Korea, [6]Korea Center for Disease Control & Prevention, Republic of Korea, [7]Seoul National University, Republic of Korea, [8]Kosin University, Republic of Korea

Culex tritaeniorhynchus is the main Japanese encephalitis (JE) vector in the Republic of Korea (ROK). However, 26 of JE cases were reported in 2010 and vector control of JE should be need. Insecticide resistance of the JE vector mosquito has been one of major obstacles for effective control. In the ROK, few resistances of Cx. tritaeniorhynchus have been reported for the recent five years and accurate resistance status of the vector mosquito should be monitored for effective control. The insecticide resistances of field collected Cx. tritaeniorhynchus from Busan-si (designated BRCT population) and Jeonju-si (JRCT population) to 10 different insecticides were evaluated with an emulsion bioassay and an insecticide resistance related enzyme assay. Enzyme levels of acetylcholinesterase (AChE), non-specific esterases (NSE), glutathione S-transferases (GST) and mixed function oxidases (MFO) were evaluated with micro plate reader. A half of resistance ratio (RR50) values of BRCT population to all tested insecticides were 1.1-2.3 fold higher than those of JRCT population, except chlorpyrifos (RR=0.38). An enzyme activity between BRCT and JRCT populations in level diagram was significantly different and enzyme activities of BRCT population also were higher than the JRCT population, except β-NSE. These results allowed us to simply and effectively monitor the levels of resistance in filed collected mosquito populations with a smaller sample. Further studies on enzyme assay to evaluate resistant level of mosquitoes depending on a kind of insecticide should be need for effective insecticide resistance monitoring.

Population density and *Plasmodium vivax* infection rates of *Anopheles* mosquitoes in the malaria epidemic areas, Incheon-si, Gyeonggi-do and Gangwon-do, in the Republic of Korea

Tae Joon Lee[1], Sun Jae Bang[2], Myung-Deok Kim[3], E Hyun Shin[4], Kyu Sik Chang[5]

[1]Gangwon Institute of Health & Environment, Republic of Korea, [2]Gyeonggi Institute of Health & Environment, Republic of Korea, [3]Incheon Institute of Health & Environment, Republic of Korea, [4]Korea Center for Disease Control & Prevention, Republic of Korea, [5]Korea Center for Disease Control & Prevention, Republic of Korea

The vector mosquito is one of important factors in transmission of vivax malaria. To effectively management vivax malaria, ecological monitoring of vector mosquitoes, such as distribution and vivax infection rates, must be need. Population density and vivax infection rates of vector mosquitoes were monitored in Incheonsi, Gyeonggi-do and Gangwon-do near Demilitarized zone (DMZ) in Northern part of the ROK with black light traps from April to October for 10 years, 2001 to 2011. The highest malaria cases were reported in 2006 and 2007 and a mean population density of vector mosquitoes during mosquito season in the years was higher than that of other years since 2001. However, in 2004 and 2011 malaria cases and density of vector mosquitoes were lower than those in other years since 2001. Population density of vector mosquito at monitoring areas in 2011 decreased over 80% than those for recent three years. The decrease of vector mosquitoes seem to be resulted from heavy rain and decrease of blood source by foot-and-mouth disease virus, Aphtae epizooticae, when considering data of Korea meteorological administration and Statistics Korea. High precipitation (mm) over 50% and increased rainy days during mosquito season may disturb blood feeding action of vector mosquitoes and expansion of population density. Plasmodium vivax infection rates of vector mosquitoes in Gangwon-do and Gyeonggi-do in 2011 more decreased as 0.12% and 0.36%, respectively, than those in the recent three years. Further studies on relationships among climate factors, vector density and patients should be need.

Tissue-specific promoter for the development of transgenic silkworm, *Bombyx mori*

Seung-Won Park[1], Tae-Won Goo[2], Seong Ryul Kim[3], Seok-Woo Kang[4], Gwang-Ho Choi[5]

[1]National Academy of Agricultural Science, Republic of Korea, [2]National Academy of Agricultural Science, Republic of Korea, [3]National Academy of Agricultural Science, Republic of Korea, [4]National Academy of Agricultural Science, Republic of Korea, [5]National Academy of Agricultural Science, Republic of Korea

We have characterized that a sw17255 gene was expressed in hemocyte-specific tissues of the silkworm, Bombyx mori L. (Lepidoptera: Bombycidae). To determined core promoter region, 10 different partial mutant clones were tested by luciferase assay in the Sf9 cells. About 1.5 kb promoter shows higher luciferase activity then constitutive promoter (BmA3). To verify tissue-specific expression, we analyzed real-time quantitative RT-PCR using the highly expressed endogenous Actin RNA as an intrinsic reference. Here to determine the core promoter region, 4 different partial mutant clones were tested using the luciferase assay in the silkworm by direct injection of target plasmid DNAs. It was verified that the sw17255 core promoter region contains elements that regulate the expression of this gene in hemocyte tissue; the selected promoter region spans nucleotides -1 to -2,112 upstream of the start codon. The promoter candidate [E] (-579/-1) showed more than 1.67 fold transcriptional activity compared to control promoter activity. Development of this promoter directly or indirectly specifically inducible in the tissue is very useful to make recombinant proteins in the transgenic silkworm.

Functional genomics of yellow-g and yellow-g2 of the Asian tiger mosquito, *Aedes albopictus*

Sung Hyun Kim[1], Mi Young Noh[2], Yeon Soo Han[3], Yasuyuki Arakane[4]

[1]Chonnam National University, Republic of Korea, [2]Chonnam National University, Republic of Korea, [3]Chonnam National University, Republic of Korea, [4]Chonnam National University, Republic of Korea

Pigmentation or melanization is an important physiological event in insects and is involved in cuticle tanning, wound healing and encapsulation as a defensive response. Dopachrome-conversion enzyme (DCE, yellow) significantly accelerates the pigmentation/melanization reaction. A similar pigmentation/melanization process is used in the tanning (hardening and darkening) of the egg chorion in some mosquitoes. The goal of this study was to determine whether ovary-specific yellow genes (AalY-g and AalY-g2) are required for rigidity of the egg of the asian tiger mosquito, Aedes albopictus. Full-length of cDNAs for AalY-g and AalY-g2 were cloned and sequenced. Developmental- and tissue-specific expression patterns of these two genes were analyzed by RT-PCR and real-time PCR. AalY-g and AalY-g2 encode a protein of 379 and 373 amino acids containing a signal peptide. The transcripts of both genes were detected in the ovary of mature adult females only after blood feeding (48 to 72 h post-blood meal). When dsRNA for AalY-g or AalY-g2 was injected into blood fed-adult females, the treated females did oviposit. However, the outermost colorless exochorion of the eggs was fragile and partially peeled off. Some of the eggs (~5%) were not melanized and most of them delayed initial melanization (~3 h post-oviposition) of their endochorion. When the melanized-eggs (72 h post-oviposition) were placed in dry condition, approximately 50% eggs were collapsed. These results support the hypothesis that Yellow-g and Yellow-g2 are critical in chorion tanning, vitelline membrane hardening and desiccation resistance of mosquito eggs.

Predation and control efficacies of *Misgurnus mizolepis*(Cypriniformes: Cobitidae) toward *Culex pipiens molestus* (Diptera: Culicidae) and fish toxicity of temphos in laboratory and septic tank conditions

Sung Chun Chae[1], Young Hyun Kwon[2], Kyung Il Min[3], Hyung Soo Kim[4], Nam-Jin Kim[5], Jun-Ran Kim[6], Bong Ki Son[7], Young-Joon Ahn[8]

[1]Seoul National University, Republic of Korea, [2]Seocho Public Health Center, Republic of Korea, [3]Seocho Public Health Center, Republic of Korea, [4]Seocho Public Health Center, Republic of Korea, [5]Henkel Home Care Korea Ltd, Republic of Korea, [6]College of Agriculture and Life Sciences, Seoul National University, Republic of Korea, [7]Seoul National University, Republic of Korea, [8]Seoul National University, Republic of Korea

An assessment was made of the biological control potential of mud loaches, Misgurnus mizolepis Gunther (Cypriniformes: Cobitidae), toward Cx. pipiens molestus larvae, in laboratory and septic tanks. Results were compared with those of temephos 20% emulsifiable concentrate (EC). In the lab tests, all mud loaches survived on sedimentation chamber and effluent chamber water of aerobic septic tanks (ASTs), whereas all mud loaches died within 3?12 h after introduction into sedimentation chamber and effluent chamber water of anaerobic septic tanks (AnASTs). Gill hyperplasia and hemorrhages at the bases of pectoral fins were detected in all dead mud loaches. These appear to be caused by bacterial disease because the physical and chemical parameter values of the AST and AnAST water were highly variable. A mud loach consumed an average of 951?1,087 larvae of Cx. p. molestus in the AST water at 24 h. The temephos formulation did not cause fish mortality at a company recommendation rate (10 ml/ton) in the AST water. In the AST experiment, predation of mosquito larvae by mud loaches at a release rate of 900 mosquito larvae/fish resulted in complete mosquito control from the 3rd or 7th d after treatment (DAT) through the end of the survey period for 18 wk, compared with two temephos 20% EC-treated AST water (reduction rate, 41 and 33% 28 DAT). Mud loaches merit further study as a potential biological control agent for the control of mosquito populations in septic tanks.

Molecular detection of tick-borne pathogens in ixodid ticks from Pakistan

Zafar Iqbal[1], Nabanita Mukherjee[2], Steven Adamson[3], Zia-ud-Din Sindhu[4], Shafiq Ullah[5], Arijo Abdullah[6], Dmitry Apanaskevich[7], Shahid Karim[8]

[1]The University of Southern Mississippi, U.S.A., [2]The University of Southern Mississippi, U.S.A., [3]The University of Southern Mississippi, U.S.A., [4]University of Agriculture, Pakistan, [5]University of Agriculture, Pakistan, [6]Sindh Agriculture University, Pakistan, [7]Georgia Southern University, U.S.A., [8]The University of Southern Mississippi, U.S.A.

Ticks are an example of efficient ecto-parasites that blood-feed on variety of hosts including humans, domestic and wild animals. Ticks transmit a variety of bacterial, protozoan, and viral disease agents during blood feeding on the host. The aim of this study was to evaluate tick-borne infection in ticks from different ecological regions of Pakistan infesting ruminants. Ticks (?574) were collected from ruminants and identified to species level. The ticks were identified as Hyalomma anatolicum anatolicum, Hyalomma dromedarrii, Rhipicephalus microplus, Rhipicephalus sanguineus, and Argus persicus. The prevalence of Spotted Fever Group Rickettsia (SFGR), Babesia, and Theileria wwere examined using Polymerase Chain Reaction (PCR). The nucleotide sequence similarity of the PCR products revealed infection of Theileria, Babesia, and SFGR species. Additionally, the results of pathogen-load and the microbial community residing in single H. anatolicum anatolicum and R. microplus by using 454-based pyrosequencing approach will be discussed.

Evaluation of two storage mites life tables on dried oyster mushroom and their harmful effects at different constant temperatures

Nevin Ahmed[1], Mo Wang[2]

[1]Huazhong Agricultural University, China, [2]huazhong agricultural university, China

The current study aimed to estimate the influence of three constant temperature (20 ºC, 25 ºC and 30 ºC) on the population growth, damage effects and life table of two stored product mites (Tyrophagus putrescentiae and Aleuroglyphus ovatus) reared on oyster mushroom at 80 % relative humidity (R.H.) and a photoperiod of 14 light: 10 dark (L: D). The rate of the increase (r) was (0.161 and 0.111), (0.175 and 0.122) and (0.154 and 0.094) at 20, 25 and 30 °C due to the effect of T. putrescentiae and A. ovatus, respectively. The highest decreases in the weight of oyster mushroom were 18.23 % and 12.50 % at 25 ºC in the presence of 320 individuals of T. putrescentiae or A. ovatus, respectively. The female longevity of T. putrescentiae and A. ovatus varied from 34.74 and 45.37days at 20 ºC to 23.17 and 31.16 days at 25 ºC and to 17.55 and 24.44 days at 30 ºC, respectively. The results also showed that net reproductive rate (R0), population doubling time (PDT) and Mean generation time (T) for T. putrescentiae and A. ovatus affected negatively as temperatures increased. In contrast, both intrinsic rate of increase (rm) and Finite rate of increase (λ) increased as results of temperature decreased. The highest rm of T. putrescentiae (0.265) and A. ovatus (0.140) were noticed at 25 ºC. Conversely, the lowest rm for T. putrescentiae (0.171) and A. ovatus (0.09) were recorded at 20 ºC.

Predictors of dengue fever and dengue haemorrhagic fever in Punjab, Pakistan

Saleem Muhammad Rana[1], Asma Abdul Latif[2], Tanveer Akhtar[3]

[1]Health Services Academy, Quide-i-Azum University, Pakistan, [2]Health Services Academy, Quide-i-Azum University, Pakistan, [3]Health Services Academy, Quide-i-Azum University, Pakistan

Purpose of study: This study was conducted to assess the future threat of Dengue Fever and Dengue Haemorrhagic Fever in Punjab, Pakistan Type of Study: Prospective descriptive study. Place and duration of Study: Primary data of laboratory confirmed cases was collected from all levels of health facilities of public and private sector. Disease vectors were collected from Lahore. Data of rainfall and temperature were obtained from website of department of meteorology Pakistan to determine the potential values. Methodology: Vector-borne diseases are the serious health problems worldwide, including Pakistan. Coverage of control interventions and physio-environmental factors were also analyzed. Results: In 2008 there was a largest epidemic of dengue fever in Punjab and 1382 cases were reported in 16 districts out of 36, which increased in number of cases up to 5724 and district up to 34 in 2010. Our results suggest that rainfall and temperature were predictive of the abundance of Ae.aegypti and Ae.albopictus and in time interventions have positive significant impact on disease transmission. Conclusion: This paper offered useful information that the climatic and physio-environmental factors like built-up, agriculture, water bodies and forest areas have different influence on the dengue fever incidences. This will help in focusing the preventive measures being applied on priority in very high and high-risk zones and save time and money. No special funds were used for this study.

Daily survival, anthropophily and the role of major *Anopheline* vectors in malaria transmission in South west Nigeria

Kolade Tahiru Ibrahim[1], Tonye Grace Okorie[2]

[1]*University of Ibadan, Nigeria,* [2]*University of Ibadan, Nigeria*

To evaluate the vector efficiency of Anopheles gambiae s.s, An.arabiensis and An.funestus, An.moucheti and An.nili in transmitting falciparum malaria in three villages in South west Nigeria, daily survival and feeding host preferences were studied between January 2000-December 2003, and July?December 2004. Mosquitoes were collected by human?landing catches (HLC) and pyrethrum spray catches. Morphological and molecular characterisation, host blood meal preferences, parity and daily survival, sporozoite and entomological inoculation rates assessment of the anophelines were performed. A total of 20393 adult female anophelines belonging to twelve different species were caught. Out of these, the major vectors; Anopheles gambiae s.s, An.funestus, An. arabiaensis, An.nili and An.moucheti constituted 77.83%, while the secondary vectors comprised only 22.17%. There was a substantial indoors to outdoor variation and seasonality in the distribution of the Anopheles population. All the five species showed similar nocturnal biting patterns and were sympatrically involved in malaria transmission simultaneously or replacing each other seasonally. The mean anthropophagic tendency of the major malaria vectors was high with the mean HBI >75%. The annual mean parous rate of 59.15% was recorded among the major vector species with the highest rate of 76.96% in An.funestus population and the least rate of 43.07% in An.nili. Mean probability of daily survival of malaria vectors was 0.76, with annual mean life expectancy of 13.85days and the expectation of infective life was short with a mean of 4.79 days. The average infection and Entomological inoculation rates, among the major anophelines were 6.52% and113 bites/person/year, respectively.

The effect of oxidative stress on the DDT insecticide resistance phenotype and life history of the major Malaria vector *Anopheles arabiensis*

Shune Oliver[1], Basil Brooke[2]

[1]*National institute for communicable diseases, South Africa,* [2]*National institute for Communicable Diseases, South Africa*

The upregulation of oxidative stress related transcripts has been described in wild, bloodfed Anopheles arabiensis, but no further studies have been reported on the relationship between oxidative stress and insecticide resistance. This study examines the effect of oxidative stress on the expression of DDT resistance and life history of laboratory-reared An. arabiensis. The effect of multiple bloodmeals on DDT resistance was evaluated by WHO bioassay. The effect of protein supplementation was examined by allowing DDT susceptible and resistant adult An. arabiensis continuous access to 10% sucrose supplemented with 3.4x 10-4 µM recombinant human insulin and measuring their longevity. To examine the effect of the insulin on DDT resistance, adults were bioassayed after three days access to 5.9x 10-4 µM recombinant human insulin. The difference in the capacity of susceptible and resistant strains to cope with insecticide and superoxide generated oxidative stress was determined by quantifying oxidative stress markers and the activity of oxidative stress relieving enzymes. Protein supplementation in the form of insulin significantly decreases the lifespan of DDT susceptible, but not resistant, females. It also results in a small but significant decrease in DDT resistance despite the presence of a knockdown resistance (kdr) genotype. Multiple bloodmeals cause a significant increase in DDT resistance after 15 days, suggesting that females that have taken multiple bloodmeals are more likely to survive DDT intoxication at the critical age for Plasmodium transmission. This is one of the first studies to report the biochemical effects of oxidative stress on insecticide resistance.

Effect of Mohlolo bait on age- related *Blatella germanica* population levels

Clarah Mbowane[1], Maboko Samuel Mphosi[2], Phatu William Phatu[3]

[1]University of Limpopo Private Bag x 1106 Sovenga 0727 South Africa, South Africa, [2]University of Limpopo, South Africa, [3]University of Limpopo, South Africa

The control strategies of cockroach populations have shifted from predominant use of insecticide sprays to the inclusion of baits in management programmes. The effect of Mohlolo bait on German cockroach populations was investigated in SOuth Africa, where the pest has attained uncontrollable status in homes.The study was conducted at Limpopo Agro-Food Technology Station (LATS) laboratory, University of Limpopo. The laboratory was maintained at 24-28d egree Celsius, ambient humidity, and a photoperiod of 10: 14 (L: D).A complete randomized design was used, with age of cockroaches as treatments. The experiment comprised of six treatments which were 1-d old, 2-d old, 3-d old, 4-d old, and 5-d old German cockroach nymphs. Mortality was recorded daily (until all the nymphs were dead. The data was subjected to the analyses of variance by using Statistics 8.1 software. Mean separation for significant treatment was achieved using the Tukey's multiple range tests at 5 % level of significance. The period of exposure to Mohlolo bait attributed 97%, 99%, 100%, 100% and 100% of total variation in 1-d, 2-d, 3-d, 4-d and 5-d old nymphs respectively, The study showed that 1-d old B. germanica nymphs are more resistance to Mohlolo bait compared to 2-d, 3-d, 4-d and 5-d days old B.germanica nymphs. According to the data, 100% mortality of 1-d old nymphs was obtained after seven days exposure to Mohlolo bait, whereas the subsequent ages could not live beyond 4 days.

Field evaluation of BG-Sentinel and BG-Mosquitito traps for filarial vector *Aedes polynesiensis* in French Polynesia

Limb Hapairai[1], Hayley Joseph[2], Michel Cheong Sang[3], Wayne Melrose[4], Scott Ritchie[5], Tom Burkot[6], Steven Sinkins[7], Herve Bossin[8]

[1]Institut Louis Malarde, French Polynesia, [2]James Cook University, Australia, [3]Institut Louis Malarde, French Polynesia, [4]James Cook University, Australia, [5]James Cook University, Australia, [6]James Cook University, Australia, [7]University of Oxford, United Kingdom, [8]Institut Louis Malarde, French Polynesia

The efficacy of the BG-SentinelTM and the BG-MosquititoTM traps was evaluated in French Polynesia against human bait catch using the CDC Backpack aspirator. Efficiency was measured by comparing collection methods in a randomized Latin-square design primarily for collection of host-seeking females of the filarial vector Ae. polynesiensis. Production of CO2 from yeast-sugar fermentation was measured (average 105 ml/min) and proved to be a suitable alternative source of CO2 where either dry ice or gas cylinder was unavailable. The various collection apparatus were tested on two typical islands of French Polynesia: the high, volcanic island of Moorea, and the low, coral island (atoll) of Tetiaroa. On Moorea, efficiency of the BG-Sentinel traps baited with either BG-lure or CO2 plus octenol were significantly more efficient than the BG-Mosquitito with BG-lure. Catch rates of BG-Sentinel or BG-Mosquitito baited with either BG-lure or CO2 plus octenol did not differ significantly to the CDC Backpack aspirator. On Tetiaroa, the operation of BG-Mosquitito was greatly affected from interference caused by rodents and consequently these traps were removed from comparison. Catch rate of the BG-Sentinel with either BG-lure or CO2 plus octenol did not differ significantly to the CDC Backpack aspirator. Both BG-Sentinel and BG-Mosquitito trap proved to be suitable efficient and convenient alternatives to the landing catch collection method for sampling Ae. polynesiensis. However, the BG-Mosquitito's poor reliability in the field and the lower quality of mosquito specimens resulting from this trap demonstrate that the BG-Sentinel is a more adapted tool for Aedes mosquito field research.

Entomological characteristics after five years of malaria control on Bioko Island, *Equatorial Guinea*

Hans Jorgen Overgaard[1], Vamsi P. Reddy[2], Simon Abaga[3], Abrahan Matias[4], Michael R. Reddy[5], Vani Kulkarni[6], Christopher Schwabe[7], Luis Segura[8], Immo Kleinschmidt[9], Michel A. Slotman[10]

[1]Norwegian University of Life Sciences, Norway, [2]Texas A&M University, USA, [3]Ministry of Health , Equatorial Guinea, [4]Medical Care Development International Inc., Equatorial Guinea, [5]Yale University, U.S.A., [6]Texas A&M University, USA, [7]Medical Care Development International Inc., Equatorial Guinea, [8]Medical Care Development International Inc. and Swiss Tropical and Public Health Institute, Equatorial Guinea and Switzerland, [9]London School of Hygiene and Tropical Medicine, United Kingdom, [10]Texas A&M University, USA

The Bioko Island Malaria Control Project (BIMCP) in Equatorial Guinea started in 2004 with the goal to reduce malaria transmission and associated morbidity and mortality on Bioko Island. In 2009 the project was extended by a second 5-year term from 2009-2013. To achieve these goals a set of integrated interventions were implemented combining vector control, effective case management, improved management of malaria during pregnancy, public communication, monitoring and evaluation, and operational research. Vector control consists of indoor residual spraying (IRS) with bendiocarb and long-lasting insecticide treated bed-nets (LLIN). Here we report the results from the human landing collections of 2009 on vector density, biting times, species composition, sporozoite rates, and entomological inoculation rates (EIR). Regular adult overnight mosquito collections were carried out by human landing collections at three sites on the island. In the northwestern Punta Europa area high human biting rates of Anopheles mosquitoes and high sporozoite rates produced an EIR of 883, the highest on the island. In this area about 100% were Anopheles gambiae s.s. The EIR in southeastern Riaba was 249 (46% An. gambiae s.s. and 54% An. melas) and in southwestern Arena Blanca 145 (almost 100% An. melas). Biting was more prevalent outdoors. Large spatiotemporal variations in mosquito density, biting activity, species composition and sporozoite rates indicate that pockets of high malaria transmission remain despite a largely successful control program. These hotspots require additional specific targeted vector control interventions, e.g. larval control or environmental management.

Natural product of Yartsa Gumba an entomo-fungal complex of Indian Himalayas

Shahid Sami Siddique
Higher Education, India

ABSTRACT Yartsa gumba or Yar-rtsa-dgun-bu is Tibetan name of an Entomo-Fungal combination between Hepialus sp. (Lepidoptera; Hepialidae) larvae and its parasitizing fungus (Cordyceps sinensis), which is traditionally used in Tibetan and Chinese System of Medicine (TCM). This medicinal entomo-fungal product is known in Chinese as Dong Chong Xia Cao (winter worm and summer plant or grass in summer and worm in winter) Yartsa Goenbub in Bhutan, Yarchagumba means herbs of life in Nepal and Tochukaso in Japan. It is also known as Caterpillar mushroom, Caterpillar fungus, vegetable wasp, plant worm, vegetable caterpillar (Cooke,1892) and in India it is commonly known as Keera Ghas. This entomo-fungal combination is known to be used for many centuries as tonic, medicine and aphrodisiac and in religious ceremonies in China, Indonesia and Upper Himalayas. The Importance of this combination is due to a fungus viz Cordyceps sinensis parasitizing the host caterpillars (Arif and Kumar 2003). In nature host (Hepialus) and parasitizing fungus (Cordycep)s both occur in difficult terrain of high altitude areas ranging from 10500-16000 feet altitude and are rare. It occurrence in high mountains at an altitude above 4000 m was noticed and reported by Garbyal 2000 & 2001. Exhaustive work has been done on high altitude insects and its biology by various workers (Mani 1995, Arif 1997, Arif & Kumar 1995, and Arif and Kumar 2002) Native occurrence of the fungus is confined to high Himalayan mountains in Tibet, Nepal, China, India, Bhutan and Sikkim at an altitude ranging from 3000-5000 m amsl.

Field efficacy of peridomestic insecticide space spraying against two *Aedes* populations in Tahiti, French Polynesia

Herve C. Bossin[1], Charles Jeannin[2], Jerome Marie[3], Stephane Loncke[4]

[1]Institut Louis Malarde, French Polynesia, [2]Institut Louis Malarde, French Polynesia, [3]Institut Louis Malarde, French Polynesia, [4]Health Department, French Polynesia

In the absence of specific treatments or vaccines, vector surveillance and control are the only measures available to suppress vector borne disease transmission. In French Polynesia, current public health interventions are based mostly on the use of chemical insecticides. The effectiveness of vehicle-dispensed peridomestic space spraying of insecticides in reducing Aedes populations was investigated in the rural village of Toahotu, Tahiti. Mean 24 hr Aedes catches using BG-Sentinel™ traps were used to evaluate the outcome of permethrin space spraying. Outdoor entomological sampling was performed before and after a single insecticide ULV application at a control and treatment site. No significant differences were observed in Aedes trap catches between control and treatment during the 3 weeks preceding the insecticide application. Immediate reduction of Aedes polynesiensis females was observed after spraying with mean trap catches significantly different between treatment and control sites. However, this difference was only transient with adult female population returning to pre-spray level after 4 to 7 days post-treatment. For Aedes aegypti, no significant difference was observed between treatment and control after spraying. A significant increase in Aedes aegypti female trap catches was observed at the treatment site 4-7 days after ULV application. Altogether, our results indicate that the effectiveness of peridomestic space spraying is very limited in time and particularly unsuitable for the control of the (indoor) population of Ae aegypti.. Our results support the development and field evaluation of innovative, more efficient, and more sustainable control methods to reduce the risk of dengue and other arbovirus transmission.

Prey preference of aquatic insects: Implications in regulation of wetland mosquitoes

Nabaneeta Saha[1], Gautam Aditya[2], Goutam Saha[3]

[1]Serampore College, Hooghly, West Bengal, India, [2]The University of Burdwan, Golapbag, India, [3]University of Calcutta, India

Wetlands are potential sites for mosquito breeding and are thus important from public health viewpoint. Chemical and microbial controls are constrained in wetlands due to prospective impact on the diverse biota. Biological control using generalist aquatic insects can serve the purpose, provided a preference for mosquito larvae is exhibited. Mosquito prey preference of three water bugs and larvae of two odonate species was evaluated using chironomid larvae, fish fingerlings and tadpoles as alternative prey. Manly's selectivity (αi) value with 95% confidence interval (CI) was estimated to judge the prey preference pattern. MANOVA and standardized canonical coefficients were used to test the density effects on the prey selectivity. The αi values indicated significant preference ($P < 0.05$) for mosquito by all the insect predators against the alternative prey as a density dependent function. On a comparative scale chironomid larvae had highest impact as alternative prey. In multiple prey experiment, the predators showed a similar preference pattern of mosquito over the alternative prey reflecting a significant ($P<0.05$) niche overlap. The results suggest that these predators can effectively reduce mosquitoes in presence of multiple alternative prey. Their use in biocontrol of mosquitoes of wetland will enhance conservation and meet the requirements of public health.

Insecticide resistance in *An. Arabiensis* from Sudan: Temporal trends and underlying mechanisms.

Hiba Abdalla[1], Lizette Koekemoer[2], Craig Wilding[3], Hilary Ranson[4], Maureen Coetzee[5]

[1]Blue Nile National Institute for Communicable Diseases - Gezira University, Sudan, [2]National Institute for Communicab/University of the Witwatersrand/ School of Pathology, South Africa, [3]Liverpool school of Tropical Medicine and Hygiene, United Kingdom, [4]Liverpool School of Tropical Medicine, United Kingdom, [5]Malaria Entomology Research Unit Wits University, VCRU/NICD, South Africa

Insecticide resistance is a real threat to the sustainability of any malaria vector control program in Africa. Malaria vector control in Sudan relies mainly on indoor residual spraying (IRS) and the use of LLINs. Studies on the molecular mechanisms conferring insecticide resistance are important in both understanding the molecular basis of resistance and to minimising its impact on disease control. WHO susceptibility tests were carried out to detect resistance to DDT, fenitrothion, bendiocarb, permethrin and deltamethrin. Molecular assays were carried out to determine kdr allelic frequencies. The gene-expression profile of a highly permethrin-resistant population of An. arabiensis from central Sudan was characterized using a unique whole-genome microarray. Throughout the surveys An. gambiae s.l. populations from all sites were fully susceptible to bendiocarb and fenitrothion. However, high frequencies of resistance to DDT and pyrethroids were seen in three sites. This study reported seasonal variations of insecticide resistance from all sites. The 1014F kdr allele was present in all four populations tested and the presence of this allele was significantly correlated with resistance to pyrethroids and DDT ($P < 0.05$). The 1014S allele was not detected in any of the populations tested Two cytochrome P450s were significantly over expressed in the survivors, CYP6 Z3 (10.2 fold) and CYP6P3 (6.7 fold). This is the first study to demonstrate P450s in An. arabiensis from Sudan. The findings add to the understanding of the genetic basis of insecticide resistance in wild mosquito populations from Sudan.

Contact toxicity of *Lavandula angustifolia* Mill and *Zataria multiflora* Boiss essential oils against *Callosobruchus maculatus* adults (Coleoptera: Bruchidae)

Gholamhossein Moravvej[1], Zahra Golestani Kalat[2], Arezoo Heydarzade[3]

[1]Ferdowsi University of Mashhad, Iran, [2]Ferdowsi University of Mashhad, Iran, [3]Ferdowsi University of Mashhad, Iran

In last decades, many researches have been down on use of botanical compound especially essential oils as insecticides. In the present study, the contact toxicity of Lavandula angustifolia and Zataria multiflora essential oils were evaluated on both sexes of 1-2 day-old C. maculatus adults at 30±1ºC, 60±5% RH and dark condition. Essential oils were obtained by hydrodistilation. The toxicity of oils against males and females were positively and significantly associated with concentration. On the basis of LC50 ratios and their 95% confidence limits, there was no significant difference between sensitivity of males and females. The LC50 values were 719 and 598 µl.m-2 against males and 787 and 738 µl.m-2 against females for L. angustifolia and Z. multiflora, respectively. Both oils showed no toxicity on cowpea (Vigna unguiculata) seed germination. Based on the analysis by GC-MS, the main compounds of L. angustifolia oil were linalool (42.8%), 1,8-cineol (23.4%), rosefuran epoxide (14%), menthone (6.8%), isomenthol (5.2%) and dihydro carvone (trans) (4.3%) and those of Z. multiflora oil were thymol (55%), linalool (37.8%) and p-cymene (7.2%). The results suggested that L. angustifolia and Z. multiflora essential oils might be suitable alternatives to conventional pesticides for protecting pulses against C. maculatus adult.

The first report of the aphid *Cinara pini* from Iran and study on its morphology and biology

Gholamhossein Moravvej[1], Javad Karimi[2], Amirhossein Nazemi[3]

[1]Ferdowsi University of Mashhad, Iran, [2]Ferdowsi University of Mashhad, Iran, [3]Ferdowsi University of Mashhad, Iran

During a survey on pine Pinus mugo Turra pests in April 2010 in Mashhad, the aphid species of Cinara pini (Linnaeus, 1758) was observed in abundant populations particularly on the seedlings. The aphid belongs to the subfamily Cinarinae and family Lachnidae. The mean adult size was 2.5 to 2.9 mm. The base of final antennal segment has fewer than 4 hairs. The final rostrum segment is longer than the basal diameter of cornicles or equals to or slightly longer than the second segment of hind leg tarsus. The aphid had three nymphal instars lasting 10 days in greenhouse conditions (25±2 °C, 45±5 % r.h.). The period from adult emergence until first reproduction lasted 48 hours. The reproductive period lasted 13 days during which a mean of 36 nymphs were deposited. The total length of one generation was 25 days.

Molecular mechanisms of insect diapause: Supplementing alanine enhances cold tolerance in non-diapause *Calliphora vicina* larvae

Paul Christopher Coleman[1], Jeffery S. Bale[2], Scott A L. Hayward[3]

[1]University of Birmingham, United Kingdom, [2]University of Birmingham, United Kingdom, [3]University of Birmingham, United Kingdom

Winter provides a period of extreme cold and limited resource availability. To survive winter many temperate insects enter diapause, a period of reduced metabolic activity. Diapause synchronises development with favourable conditions, and is associated with an enhanced ability to tolerate cold exposure. In the blowfly, Calliphora vicina, non-diapause larvae freeze (SCP) at -11.7+1.3°C and display 50 % mortality (LT50) after 5.1 days at -4 °C. Diapause larvae have an enhanced ability to tolerate the cold, with a mean SCP of -18.9+0.6°C and LT50 after an astonishing 42.1 days at -4°C. The physiological responses of diapause are well understood, but little is known about the underlying molecular mechanisms. A metabolomic analysis identified diapause and non-diapause larvae to follow distinct development pathways; with metabolites such as alanine and proline up-regulated during diapause. Alanine stabilises enzyme structure and function at low temperatures, and proline is known to increases cold tolerance in many species. Supplementing diets of non-diapause C. vicina with alanine and proline allowed us to identify what role these amino acids have in inferring cold tolerance. Non-diapause larvae supplemented with an alanine diet displayed a lowered SCP of -13.6 +1.0 °C and LT50 of 15 days at -4 °C, an increase in cold tolerance when compared to non-supplemented larvae (SCP of - 11.7+ 1.3 °C and an LT50 of 5.1 days). However, supplementing with proline failed to enhance cold tolerance. In conclusion, diapause represents a distinct development pathway, in which alanine has an important role in ensuring survival during the winter period.

Effect of essential oils formulation against *Plutella xylostella* L

Purwatiningsih n Purwatiningsih[1], Neil Heather[2], Errol Hassan[3]

[1]*University of Queensland, Australia,* [2]*University of Queensland, Australia,* [3]*University of Queensland, Australia*

Four essential oils formulations originated from Melaleuca alternifolia and Eucalyptus were evaluated for their insecticidal effect against Plutella xylostella L (Lepidoptera: Plutellidae). This insect is the major pest of Brassica plants. The essential oil formulations used in this study are funga-t-ol; gamma-t-ol; funga-t-ol and neem oil; and gamma-t-ol and neem oil. All the essential oils examined revealed insecticidal effects and antifeedant activities against P. xylostella larvae. By using leaf dipped methods, the oils formulation reduced the larval and pupal weight. Furthermore, malformation during pupal stage was also recorded. Oviposition deterrent effects when an adult stage was exposed to treated leaves were found to be significant (P = 0.0001) compare to control. No eggs have been laid at concentration above 4.6% for all essential oils applied. The toxicity assay by looking the LC50 indicates the insecticidal potential in the essential oil of gamma-t-ol is more toxic than funga-tol when the oil applied independently. However, the presence of neem oil into funga-t-ol and gamma-t-ol increased their insecticidal activity by looking at the higher antifeedant index, the lower LC50, insect weight and insect fecundity. Therefore, these results suggest that essential oils from the studied plants may be used against insect pests in P. xylostella. In addition, it appears that neem oil addition can increase the efficacy of funga-t-ol and gamma-t-ol.

Thermal tolerance, acclimation responses and voluntary running performance of meat ants (*Iridomrymex purpureus*): Implications of climate change on common species

Nigel Andrew[1], Robert Hart[2], Myung-Pyo Jung[3], John Terblanche[4]

[1]University of New England, Australia, [2]University of New England, Australia, [3]National Academy of Agricultural Science, Republic of Korea, [4]Stellenbosch University, Private Bag X1, Matieland, South Africa

Understanding thermal performance and limits to activity or survival of is of fundamental importance to predicting the effects of climate change on terrestrial organisms. Here we examine several traits of physiological tolerance and voluntary running performance on an Australian meat ant (Iridomrymex purpureus), and how these traits changed with acclimation to varying temperatures in the laboratory and between summer and winter seasons. Specifically, we predict that meat ants will exhibit 1) limited rapid-cold hardening responses due to their high mobility and behavioural flexibility, 2) pronounced acclimation and seasonal responses of thermal tolerance owing to high levels of seasonal variability and predictability in their natural habitat, and 3) that voluntary performance in the field is temperature-dependent and similar to laboratory thermal performance curves and 4) that acclimation responses of running speed will be limited. We discuss our results in the context of climate change impacts on common dominant species, and the importance of local microclimate recordings.

Does size matter? Insights from the life history traits of dengue vectors in Kolkata, India

Soumyajit Banerjee[1], Gautam Aditya[2], Goutam Kumar Saha[3]

[1]University of Calcutta, India, [2]The University of Burdwan, India, [3]University of Calcutta, India

In mosquitoes, morphological features are often viewed as life history traits providing indication about individual and population level fitness. Fitness of mosquitoes enables predictions about prospective population build up and disease transmission potential. Using body size as surrogate of fitness, an estimation of its correlation with various life history traits of the dengue vectors Aedes aegypti and Ae. albopictus was made. Adult body size expressed in terms of wing length and dry biomass was significantly positively correlated with longevity and fecundity of both Aedes species. Larval developmental time and pupal weight were positively correlated to wing length, biomass and nutritional reserves in the adult Aedes mosquitoes. Species specific and sex specific differences were prominent for these measures and Ae. aegypti being larger in body size than Ae. albopictus. It is apparent that larval development time is key determinant of body size that in turn assures fitness of adult Aedes mosquitoes. Since dengue transmission is linked to longevity and fecundity, body size of Aedes mosquitoes is a key factor in dengue epidemiology. Aedes mosquitoes will be favoured by natural selection for bigger body size to ensure higher reproductive success and thus sustenance of a larger population; it would also increase the risk of dengue in human. Thus factors favouring the development of individual larva into bigger adults would indirectly promote dengue prevalence in a geographical area. Body size therefore is an important morphological feature that matters in dengue transmission and prevalence.

Managing Potato virus Y (Potyviridae): The role of aphid (Aphididae: Hemiptera) olfaction in identifying potential crop border plants

Michelle Louise Schroder[1], Robert Glinwood[2], Ben Webster[3], Rickard Ignell[4], Kerstin Kruger[5]

[1]University of Pretoria, South Africa, [2]Swedish University of Agricultural Sciences, Sweden, [3]Swedish University of Agricultural Sciences, Sweden, [4]Swedish University of Agricultural Sciences, Sweden, [5]University of Pretoria, South Africa

Potato virus Y (PVY) causes downgrading of seed potato quality leading to severe economic losses. Crop borders, consisting of virus non-host plants, can reduce the incidence of non-persistently transmitted viruses, such as PVY. Immigrating aphid vectors land in high numbers at the edge of a field. Planting a non-host plant for the virus displaces the border by acting as a virus sink. Using a plant species/cultivar preferred by aphids would considerably strengthen the effect. The aim of this study is to select a border plant from maize and wheat cultivars that is more attractive to aphids than potato. The olfactory response of the PVY vectors Rhopalosiphum padi (L.) and Macrosiphum euphorbiae (Thomas) (Hemiptera: Aphididae) to three maize, potato and wheat cultivars each (referred to as cultivars 1, 2 and 3) was evaluated using an olfactometer. Rhopalosiphum padi was attracted to odours from maize cultivar 2, potato cultivar 3 and wheat cultivar 2. Macrosiphum euphorbiae spent more time in treated arms of maize cultivar 2 and 3, and wheat cultivar 2 and 3. Analysis of plant volatile profiles by gas chromatography/mass spectrometry revealed quantitative and qualitative differences in the volatile profiles of the crop cultivars, potentially explaining the observed differences in cultivar preferences of the aphids. In regions where R. padi and M. euphorbiae are abundant maize cultivar 2 and wheat cultivar 2 may have the highest potential as crop border plants.

Characterization of resistant factors in faba bean (*Vicia faba* L.) cultivars against cowpea aphid (*Aphis craccivora Kosch.*) using Electrical Penetration Graph (DC-EPG)

Alan Soffan[1], Salem Safer Alghamdi[2], Abdulrahman Saad Aldawood[3]

[1]King Saud University, Saudi Arabia, [2]King Saud University, Saudi Arabia, [3]King Saud University, Saudi Arabia

Potential resistance of five faba bean (Vicia faba L.) cultivars against cowpea aphid (Aphis craccivora Kosch.) (Homoptera:Aphidae), was characterized through colony-development study, biological study, and feeding behaviour, using Electrical Penetration Graph (DC-EPG). The last two experiments were conducted by distinguishing whole plant and detached leaf assays. Colony-development study ranked the cultivars from the highest resistance to susceptible level into Gazira 2>commercial 'Misr'>Giza 3 improved>Goff 1>Misr 1. The aphid biological study (whole plant) confirmed the highest resistant level was found in Gazira 2 among five selected faba bean cultivars, which was indicated by relatively low total numbers of progeny, shorter reproductive time, and longest total longevity, although it did not differ significantly. In feeding behaviour study, the different resistant levels among the five faba bean cultivars were not due to surface or phloem tissue factors, but rather because of the duration of stylet derailment (waveform F), in which whole plant Gazira 2 had the longest duration, however, this was not retained in the detached leaf. Principle component analysis for some selected feeding parameters showed significant difference in aphid performance between whole plant and detached leaf. The combination of colony-development and feeding behaviour studies using DC-EPG shown to be an effective way to locate the resistant factors in faba bean cultivars against cowpea aphid.

Study of life history of *Hemipteroseius indicus* (Acari: Otopheidomenidae) parasitic on *Dysdercus koenigii* (Hemiptera: Pyrrhocoridae) in Kolkata, India

Poulami Sarangi[1], Salil Kumar Gupta[2], Goutam Kumar Saha[3]

[1]University of Calcutta, India, [2]University of Calcutta, India, [3]University of Calcutta, India

Dysdercus koenigii is the key pest of cotton and several other crops of Malvaceae throughout tropical and subtropical parts of the world. India being the global second largest producer of cotton suffers from continuous retarding production due to damage to the host plants by Dysdercus koenigii. Hemipteroseius indicus was found to parasitize the gregarious pest. The life cycle of Hemipteroseius indicus on Dysdercus koenigii was studied under laboratory condition in Kolkata, India at two temperature regimes of 19 °C and 33°C. To each of the cotton seedlings with cotton balls and uninfested pests, single gravid female mite (obtained from pure culture) was released on the dorsal surface of the abdomen and a replicate of 15 such seedling were set up. After 24 hours when the eggs were found laid, the females were removed and the eggs were observed every 24 hours till they hatched and reached the adult stage. During summer the males and females have a higher longevity (male: 15.16 ± 0.60, female: 18.84 ± 0.63) and fecundity (16.25 ± 1.20) as compared to winter (♂LONG: 8.33 ± 1.20, ♀LONG: 11.13 ± 0.72 and fecundity= 0.79 ± 0.08). The difference in the duration of other stages too, at two temperatures was significant which may be an indication of differential life history modification due to thermal variation. Thus the study highlights thermal tolerance and threshold of a natural enemy which is a critical factor in the evaluation of its suitability as a biological control agent.

Effects of gibberellic acid on hemolymph antioxidant enzymes of *Galleria mellonellaL.*(Lepidoptera: Pyralidae)

Sumeyra Nur SANAL[1], Hulya Altuntas[2], Sanem Cakar[3]

[1]Anadolu University, Turkey, [2]Anadolu University, Turkey, [3]Anadolu University, Turkey

The impacts of the plant growth regulator, gibberellic acid (GA3) given in diet on the activity of Glutathione S-transferase (GST), Catalase (CAT) and Superoxide dismutase (SOD) which are antioxidant enzyme in hemolymph were investigated using Galleria mellonellaL. (Lep.: Pyralidae) larvae. G. mellonella last instar larvae were reared in the laboratory at 25 ± 2 °C, 60 ± 5 % relative humidity, and a photoperiod of 12:12 h. Assays with GA3 were also carried out in the same laboratory condition. To investigate the effects of different doses of GA3 (50 to 5,000 ppm), enzyme activities were analyzed using spectrophotometry and enzyme-linked immunosorbent assay (ELISA) methods. Exposure of G. mellonella to a diet containing GA3 resulted in a remarkable increase in the activity of GST at 200 ppm with respect to control and other doses. The activity of GST increased at 200 and 500 ppm because of inhibiting effect of GA3. The activity of CAT in the hemolymph of last instar larvae increased significantly at higher doses > 100 ppm compared with untreated larvae. This trend in increase was not dose-wise except for the significant increase at 5,000 ppm when compared to that of untreated and all treated groups. Consequently, our results showed that GA3 is effective on the antioxidant defense system of insects as a source of free radical. Therefore, we suggest that the increase or decrease in the activity of GST, SOD and CAT in larvae may indicate a physiological adaptability to compensate for GA3-induced stress.

Novel interactions of a cypovirus in the *Heliothis virescens* and *Campoletis sonorensis* host-parasitoid system.

Juliane Deacutis[1], Philip Houtz[2], Bruce A. Webb[3]

[1]*University of Kentucky, U.S.A.,* [2]*University of Kentucky, U.S.A.,* [3]*University of Kentucky, U.S.A.*

Some viruses, notably the ascoviruses, are reliant upon parasitoid wasps for horizontal transmission between their lepidopteran hosts. Other viruses, the polydnaviruses, are obligate symbionts of parasitoid wasps, existing in highly commensal and evolved relationships with their parasitoid hosts. Among the viruses associated with parasitoid wasps, polydnaviruses are considered beneficial to the wasp and are essential in the parasitism of lepidopteran hosts. In contrast, the impact of ascoviruses within the wasp-host system can be detrimental to both the wasp and host. There are many viruses, however, associated with parasitoid wasps or the lepidopteran host, and little is known about their impact on the host-parasitoid system. We have recently discovered two genetic variants of a dsRNA Cypovirus (CPV) in laboratory colonies of the parasitoid wasp, Campoletis sonorensis and in the wasp's conventional host, Heliothis virescens larvae. CPVs typically cause non-lethal effects in insects and are similar, but unrelated, to Baculoviruses as the virions are occluded and protected by a polyhedral matrix. We characterized and sequenced the CPV variants and discovered a mutation in the polyhedrin-encoding segment. We then examined the unique pathologies and biological effects of these variants in our C. sonorensis and H. virescens colonies. CPVs are common insect colony pathogens, yet little is known about their effects on a complex biological system. We describe here a novel virus which appears to interact with a host-parasitoid system in a fundamentally new and intriguing way.

The preservation of extracted insects from Lower Eocene Indian amber

Nina Mazur[1], Jes Rust[2]

[1]Steinmann Institute, University of Bonn, Germany, [2]Steinmann Institute, University of Bonn, Germany

Amber preserves a diverse array of organisms from different habitats living in the amber-producing forest. The detailed analysis and comparison of amber inclusions reveals major aspects of the evolutionary history of these organisms. Indian Cambay amber was deposited about 50-52 million years ago during the Early Eocene Climatic Optimum (EECO), at a time approaching the Indian subcontinent's collision with Asia and is now located in western Gujarat, India. The fossil resin from the Vastan and Tadkeshwar lignite mines has preserved a highly diverse flora and fauna, including 22 orders and more than 60 families of arthropods so far. The source of the fossil resin were trees of the Family Dipterocarpacea, producing a class II dammar resin. Usually fossil arthropods are preserved in amber only as hollow spaces lined with a thin layer of diagenetically altered or decomposed cuticle. In sharp contrast, arthropods in Indian amber are often completely preserved including the cuticle as well as internal tissues of the embedded organisms, such as muscle tissue or the tracheal system. The poor polymerization and crosslinking of the amber, combined with the exceptionally preserved arthropods allow the complete extraction of the arthropod inclusions with different chemicals. Afterwards the isolated arthropods can be examined with scanning electron microscopy, enabling submicron resolution of morphological details, but also histological analyses, examinations with transmission electron microscopy as well as histochemical and other molecular methods are applicable.

The butterfly diversity of Huoditang, Qinling Mountain in China

Yanru Zhang
Beijing Forestry University, China

The diversity of butterflies in Huoditang area of in Qinling Mountain were investigated to test the effect of altitude on this diversity. The results showed that a total of 432 butterflies, belonging to 76 species, 42 genus and 7 families was collected. Based on the numbers of individuals and species, Nymphalidae is the dominant population in this area while Libytheidae is the rare population. As the increase of altitude, the individuals and species of butterflies first increased and then decreased. The richness index E and diversity index H decreased while the Evenness index J and dominance index C did not change obviously. The similarity indices in different altitude series were significantly different, which meant that this diversity had relations with the altitude and climate. The number of species and individuals, diversity index of butterflies were highest when the altitude is between 1500and 1600m. This area maintained highest butterfly diversity, so it should be well protected.

Rapid molecular identification of Encyrtid and Aphelinid parasitoids of soft scales (Hemiptera: Coccidae) in Californian citrus orchards using taxon-specific multiplex PCR

Paul Rugman-Jones[1], Lisa Forster[2], Robert Luck[3], Joseph Morse[4], Richard Stouthamer[5]

[1]University of California Riverside, U.S.A., [2]University of California Riverside, U.S.A., [3]University of California Riverside, U.S.A., [4]University of California Riverside, U.S.A., [5]University of California Riverside, U.S.A.

Citricola scale, Coccus pseudomagnoliarum Kuwana (Hemiptera: Coccidae), is a serious pest of citrus in California's San Joaquin Valley, but not in southern California where it is suppressed by a complex of Metaphycus spp. Mercet (Hymenoptera: Encyrtidae). This has created interest in using these (and other Metaphycus) species for biological control in the San Joaquin Valley. A critical step in assessing an organism's potential for biological control is the ability to accurately identify it. For Metaphycus spp., this currently requires slide mounted adult specimens and expert taxonomic knowledge. We present a simple, quick and accurate method to identify any life stage of the 10 major parasitoids of soft scales in California citrus, based on amplification of ribosomal DNA, using the polymerase chain reaction (PCR). This includes three multiplex-PCR protocols each of which amplify products of taxon-specific sizes, allowing direct diagnosis of taxa accommodated by the PCR. The method does not demand a highly skilled operator, requiring knowledge of only a few basic molecular techniques, and reduces identification time and cost to a fraction of that of existing methods.

The action mode of the nitroconjugated neonicotinoids with -NO2 or -CN group in cis-configuration

Haibo Bao[1], Qian Cheng[2], Jing Yao[3], Haiyan Lu[4], Zewen Liu[5]

[1]Nanjing Agricutural University, China, [2]Nanjing Agricultural University, China, [3]Nanjing Agricultural University, China, [4]Nanjing Agricultural University, China, [5]Nanjing Agricultural University, China

Neonicotinoid insecticides, such as imidacloprid, are selective agonists of the insect nicotinic acetylcholine receptors (nAChRs) with -NO2 or -CN group in trans-configuration. Insecticide resistance to neonicotinoids was reported in several insect species. In order to find out the new neonicotinoids without the cross-resistance, a series of nitroconjugated neonicotinoids with -NO2 or -CN group in cis-configuration were synthesized and proved to possess excellent insecticidal activity, but without the significant cross-resistance with the commercial neonicotinoids. The representative members, IPPA152004 and IPPA152201, were chosen to perform toxicity and pharmacology studies. IPPA152004 still acted on insect nAChRs, but discriminated between the high and low affinity imidacloprid binding sites in the brown planthopper, Nilaparvata lugens. In Xenopus oocytes co-injected with cRNA encoding Nlα1 and rat β2 subunits, the previously identified Y151S mutation in Nlα1 showed significant effects on the agonist potency of IPPA152004, which was less than that on imidacloprid. IPPA152201 showed a comparable toxicity with imidacloprid against N. lugens in a susceptible strain and had no significant cross-resistance in an imidacloprid resistant strain. IPPA152201 showed good efficacies on the isolated cockroach neurons and hybrid receptors Nlα1/β2 in Xenopus oocytes, whose responses were inhibited by MLA and DHβE. Compared to the wildtype Nlα1/β2, Y151S mutation reduced Imax of IPPA152201 and increased EC50, however, which is much smaller than that on imidacloprid.

Laboratory production of green lacewings, *Plesiochrysa ramburi* (Schneider)(Neuroptera: Chrysopidae) for augmentative biocontrol ofthe mealybug complex in cassava plantations

Charida Sattayawong[1], Siriwan Tunkumthong[2], Rattigan Submok[3], Sopon Uraichuen[4], Wiwat Suasaard[5]

[1]National Biological Control Research Center (NBCRC), Thailand, [2]National Biological Control Research Center (NBCRC), Thailand, [3]National Biological Control Research Center (NBCRC), Thailand, [4]Kasetsart University Kamphaeng Saen Campus, Nakhon Pathom, Thailand, [5]Kasetsart University Kamphaeng Saen Campus, Nakhon Pathom, Thailand

The green lacewings, Plesiochrysa ramburi (Schneider) (Neuroptera: Chrysopidae), is widespread in cassava plantations in Thailand, but at low number and for the catastrophic outbreaks of the mealybug complex in cassava in 2009, mass-production of the predators is imperative. The development of the mass-production of the green lacewings aimed to reduce cost and increase efficiency in the production of the predators. Primarily, mass-production of the preys was assessed in four densities 50, 100, 150 and 200 individuals of the mealybug, Phenacoccus manihoti, Matile-ferrero (Hemiptera: Pseudococcidae)/pumpkin, in dark room with 25±1˚C and 50±5 % RH, in four weeks duration. Each pumpkin was weighted approximate 1 kg. Number of the mealybug increased significantly ($P<0.05$), with each initial density. At the density 200 it gave 33,394.70±7,483.062 mealybugs/pumpkin, followed by 150, 100, and 50 /pumpkin, averaging 24,387.50±7,320.604, 16,479.80±3,002.616, and 10,024.93±2,161.204 /pumpkin, respectively. Later the larvae of the predators in four densities 50, 100, 150 and 200 were placed on the pumpkins which had different number of the mealybugs, obtained from the previous experiment. Among the test treatments combination of 100 mealybugs/pumpkin at the initial of experiment, i.e. averaged 16,479.80 preys/pumpkin and 100 larvae of the green lacewings/pumpkin provided the survival of larvae to adults 60.08%, yielding significant ($P<0.05$) the best combination. Ultimately from October 2010-September 2011, 18.41 million eggs of the green lacewings, with a production cost 20 US$ per one thousand eggs, were accomplished and 12.54 million larvae were disseminated for augmentative release in cassava plantations with the mealybug outbreaks.

Biology of *Bracon hebetori* Say (Hymenoptera: Braconidae) and its potential in population suppression of the black-headed caterpillar, *Opisina arenosella* Walker (Lepidoptera: Oecophoridae)

Wiwat Suasaard[1], Namphueng Chomphukhiao[2], Sopon Uraichuen[3], Paweena Buchatian[4], Kosol Charernsom[5]

[1]Kasetsart University Kamphaeng Saen Campus, Nakhon Pathom, Thailand, [2]National Biological Control Research Center (CRC), Thailand, [3]Kasetsart University Kamphaeng Saen Campus, Nakhon Pathom, Thailand, [4]National Biological Control Research Center (CRC), Thailand, [5]Kasetsart University Kamphaeng Saen Campus, Nakhon Pathom, Thailand

Bracon hebetor Say is an ectoparasitoid of the black-headed caterpillar, Opisina arenosella Walker. Because of the O. arenosella devastating outbreak in coconut plantations in Prachuap Khiri Khan province, Thailand since December 2010, biological information of the parasitoid on its insect host has to be urgently needed. The egg stage of B. hebetor was 1 day. and it had two larval instars with an average 2 days. The pupal period took 5.28±0.51 days. Female and male sagittal measurements averaged 2.09±0.26 and 2.08±0.18 mm, respectively. Transversal measurements averaged 0.57±0.07 and 0.56±0.06 mm for female and male, respectively. Female lived longer than male, averaging 8.68±5.29 and 7.59±3.37 days, respectively. Female laid averaged 166.88±18.53 eggs/female for its entire life. Additional comparative field study on the control tendency of B. hebetor as a biocontrol agent for O. arenosella was conducted in coconut plantations in the outbreak areas from January-July 2011. Eight coconut plantation plots, 1,600 sq.m each, were employed to observe the efficiency of the parasitoid in suppressing the naturally occurring O. arenosella populations. Two treatments, unreleased and released adults of B. hebetor with a rate of 200/month/plot were administered. Each treatment replicated 4 times. Sampling of the number of O. arenosella before and after release the parasitoids. Four trees/plot and four pinnate leaves/tree were randomly sampled on each sampling date. Results indicated that considerable control potential, within six months, averaged 21.22, 66.46, 35.26, 47.05, 64.96 and 71.86%, was recorded, respectively. B. hebetor tends to be a potential parasitoid species in controlling O. arenosella.

RNAi target validation of juvenile hormone related genes for developing novel insect growth regulators in the brown planthopper, *Nilaparvata lugens*

Takumi Kayukawa[1], Chieko Okada[2], Takaaki Daimon[3], Yoshitaka Suetsugu[4], Kimiko Yamamoto[5], Hiroaki Noda[6], Tetsuro Shinoda[7]

[1]National Institute of Agrobiological Sciences, Japan, [2]National Institute of Agrobiological Sciences, Japan, [3]National Institute of Agrobiological Sciences, Japan, [4]National Institute of Agrobiological Sciences, Japan, [5]National Institute of Agrobiological Sciences, Japan, [6]National Institute of Agrobiological Sciences, Japan, [7]National Institute of Agrobiological Sciences, Japan

The brown planthopper (BPH), Nilaparvata lugens, is one of the most destructive pests of rice in Japan. Thanks to the use of imidachloprid, the damage by BPH once became marginal in Japan. However, the outbreaks of BPH have been observed again after 2005 due to the migration of BPH that has developed resistance to the insecticide from China and South Asia. To solve this problem, development of new insect growth regulators (IGRs) which have different mode of actions is expected. Using the genome and transcriptome data of BPH, we have identified genes and/or cDNAs involved in the biosynthesis or signal transduction of juvenile hormone (JH), and evaluated their property for the target of new IGRs using RNAi techniques. By injecting respective dsRNA to the day 0 third instar nymphs, CYP15A1, a JH biosynthesis enzyme gene encoding a methylfarnesoate epoxidase, induced precocious adults at the fifth instar stage. While RNAi of JH acid methyltransferase (JHAMT) did not apparently affect their development. Intriguingly, in the red flour beetle, Tribolium castaneum, JHAMT RNAi induced precocious metamorphosis, but CYP15A1 RNAi didn't, suggesting the difference of importance of these genes in JH biosynthesis between two species. RNAi of Kruppel homolog 1 (Kr-h1), an early JH-inducible transcription factor, induced precocious metamorphosisis like CYP15A1 RNAi. While RNAi of the JH receptor, methoprene tolerant (Met) did not induce precocious metamorphosis but resulted in high mortality during nymphal stages. These results suggest that CYP15A1, Met, and Kr-h1 are plausible molecular targets for new IGRs counteracting the resistant BPH.

Spider mite response in citrus rootstocks is mediated by the oxylipin pathway

Blai Agut[1], Josep Anton Jacas[2], Monica Hurtado[3], Victor Flors[4]

[1]Universitat Jaume I (UJI), Spain, [2]Universitat Jaume I, Spain, [3]Universitat Jaume I (UJI), Spain, [4]Universitat Jaume I (UJI), Spain

Citrus rootstock selection has been traditionally based on its resistance to pathogens and tolerance to abiotic stress. However, the resistance to insects has been consistently neglected. Recently, it has been shown that the citrus rootstock can influence the life history of the phytophagous spider mite Tetranychus urticae. To compare the usefulness of pathogen resistance-based rootstock selection with arthropod tolerance/resistance we have performed comparative experiments of spider mite performance on Carrizo Citrange (Citrus Tristeza Virus, CTV, tolerant), Cleopatra mandarin (CTV and salt tolerant) and Sour orange (CTV sensitive and limestone tolerant). Sour orange showed reduced leaf damage symptoms and supported lower mite populations. Taking together the genetic analysis of defense pathways and the phenotype, results suggest a relevant role of the oxylipin pathway in the plant's defense against T. urticae. Nevertheless the SA-related responses cannot be excluded, since the most resistant rootstock, Sour orange, still displayed elevated levels of this hormone and PR5 marker gene expression upon spider mite infestation. Because the LOX inhibitor Phenidone totally abolished the enhanced response of Sour orange, oxylipins are probably essential signals controlling the orange tree defense responses against arthropod infestations.

Claiming the crown by primary queen and king after nuptial flight in orphaned conspecific colony

Xing Ping Hu[1], Wei Ding[2], Michael Lenz[3], Chong-Yang Lee[4]

[1]Auburn University, U.S.A., [2]Southwest University, China, [3]CSIRO Entomology, Australia, [4]Universiti Sains Malaysia, Malaysia

Of social insects, termites show the most complex and sophisticated reproductive system, which resulted in diverse colony genetic structures and behavior plasticity. A colony can be headed by a primary pair or various forms of supplementary reproductives. We report here a new reproduction in two subterranean termite species, Reticulitermes flavipes and R. malletie (Isoptera: Rhinotermitidae). In this study, we introduced a pair of queen and king after nuptial flight to orphaned worker groups from their natal colony, an alien conspecific colony, or an interspecific colony, to mimic possible colony infilation by newly swarmed dealates in the field. The pairs introduced into orphaned interspecific worker groups were killed immediately. The pairs introduced to intraspecific worker groups experienced moderate agonism. However, 100% of the pairs (n=6) survived in natal worker groups and 20% of the pairs (n=12) survived in conspecific worker groups. The survivor pairs of R. malletei were further assessed for survivorship and capacity of reproduction over a 7-week period. Five of the six pairs had both or one partner died within 25 d and neotenic reproductive were observed in orphaned worker groups. One pair survived and produced eggs at 23 d and the eggs hatched at 34 d. In all the groups, workers had a survivorship >75%. This study presents the first ethological evidence of the adoption of primary reproductive re-entering their natal or conspecific colony after a dispersal flight and show that eusociality can generate diverse reproductive systems.

Effect of pollen quality on biological control of *Tetranychus urticae* in citrus

Tatiana Pina[1], Poliane Sa Argolo[2], Alberto Urbaneja[3], Josep Anton Jacas[4]

[1]Universitat Jaume I (UJI), Spain, [2]Instituto Valenciano de Investigaciones Agrarias (IVIA), Spain, [3]Instituto Valenciano de Investigaciones Agrarias (IVIA), Spain, [4]Universitat Jaume I (UJI), Spain

Cover crops can modulate phytoseiid communities through provision of non-prey food sources as pollen. Clementine trees associated with a mono-specific cover crop of Festuca arundinacea had a more diverse and efficient phytoseiid community than those associated with a multifloral cover. Therefore, the former had better regulation of Tetranychus urticae populations than the latter. Pollen availability and quality could be behind this result because a multifloral cover offers longer provision of higher quality pollen relative to F. arundinacea. Therefore, populations of the superior intraguild predator and less efficient generalist pollen feeder Euseius stipulatus could easily increase in multifloral covers and then interfere with the biological control of T. urticae exerted by specific phytoseiid predators (Neoseiulus californicus and Phytoseiulus persimilis). To determine whether pollen quality could be behind these results, the effect of the provision of two types of pollen (F. arundinacea and Carpobrotus edulis) on the efficacy of two different life-style phytoseiid species (E. stipulatus and N. californicus) to regulate T. urticae populations has been studied under semi-field conditions. Results suggest that pollen provision does not enhance the ability of these phytoseiids to reduce T. urticae populations. However, C. edulis pollen resulted in explosive increases of E. stipulatus numbers that did not occur with F. arundinacea pollen. Therefore, poor quality pollen may prevent pollen feeders from reaching high numbers in the field. This effect could benefit phytoseiid species suffering intraguild predation by generalist pollen feeders, as in the case of E. stipulatus, the predominant phytoseiid species in Spanish citrus orchards.

Effect of nutrient and pre-infested Brinjal plants, *Solanum melongena* on the population and interaction between whitefly and competitor pest in a multitrophic System

Mohd Rasdi Zaini[1], Chesalmah Md Rawi[2], Abu Hassan Ahmad[3]

[1]Universiti Sains Malaysia, Malaysia, [2]Universiti Sains Malaysia, Malaysia, [3]Universiti Sains Malaysia, Malaysia

This study focused on the insect-pest composition on the underside of leaves of whitefly and aphid pre-infested brinjal plants fertilized with three levels of nutrients, N1 (50 ppm=0.05g/L), N2 (150 ppm=0.15g/L) and N3 (300 ppm=0.3g/L). The common insects-pests found on brinjals leaves were mainly sucking insects, for instance, whitefly (Bemisia tabaci), aphid (Myzus persicae Sulzer) and thrips (Thrips palmi). Based on the result from two cropping periods, once treatments applied on brinjal plants; nutrient levels that commonly influenced plant performance and pre-infestation by pests which scientifically known triggered chemical defense earlier, had significantly influenced the population abundance of whitefly, aphid, thrips, mite and spider mite. Other than treatments' effects on host plants, the population of whitefly evidently was regulated by other competitor pests naturally occurring in the field. High diversity of plant pests could modify the main pest population (whitefly) by either increasing or reducing and mediating the pest effect. When aphid co-exist to develop and compete with whitefly on the brinjal leaves, there was significant mutual relationship occurred under agro-ecological system particularly under rainshelter structure. Variations in population abundances and interactions of insect-pest community in a multitrophic system generate ideal opportunity to understand the community ecology more accurately.

Effect of imidacloprid and fipronil pesticide application on *Sympetrum infuscatum* (libellulidae: Odonata) larvae and adults

Hiroshi Jinguji[1], Dang Quoc Thuyet[2], Tetsuyuki Ueda[3], Hirozumi Watanabe[4]

[1]Miyagi University, Japan, [2]Tokyo University of Agriculture and Technology, Japan, [3]Ishikawa Prefectural College, Japan, [4]Tokyo University of Agriculture and Technology, Japan

The effect of imidacloprid and fipronil on Sympetrum infuscatum larvae and adults during the rice cultivation period was monitored using an experimental micro paddy lysimeter (MPL) system. Twenty-two hatched larvae were laid on the soil surface of each MPL. MPLs were treated with imidacloprid, fipronil, and the control MPL was left untreated. The pesticide concentration, S. infuscatum larval and adult populations, and larval emergence time were monitored in each MPL. The maximum imidacloprid and fipronil concentration in paddy water was 52.8 ?g/l at 1 day, and 1.3 ? g/l at 6 h, respectively, after the pesticide application. Both pesticides dissipated quickly in paddy water, with half-lives of 8.8 days and 5.4 days for imidacloprid and fipronil, respectively. The absence of S. infuscatum larvae and exuviae in the fipronil-treated MPL was remarkable. The larval survival percentage decreased to 63.6 ± 18.2%, 15.2 ± 2.6%, and 0% in the control, imidacloprid-treated, and fipronil-treated MPLs, respectively, by 9 days after transplantation. Emergence in the imidacloprid-treated MPL was also significantly lower than that in the control MPL. The observed decrease in the abundances of Sympetrum infuscatum larvae and adults in MPLs seems to be both directly and indirectly associated with nursery-box application of fipronil and imidacloprid.

Embryogenesis of tracheal gills in *Dineutus mellyi* (Coleoptera, Gyrinidae): Their subcoxal origin

Shintaro Komatsu[1], Yukimasa Kobayashi[2]

[1]*Tokyo Metropolitan University, Japan,* [2]*Tokyo Metropolitan University, Japan*

The larvae of the Gyrinidae are unique in having 10 pairs of tracheal gills; eight pairs of them in the first eight abdominal segments, and two pairs in the ninth segment. In the present study, the formative process of the tracheal gills in the embryo of a whirligig beetle, Dineutus mellyi, was described from observations based on light and scanning electron microscopy. A pair of lateral tracheal gills (LTGs) of the first abdominal segment originates forms appendage-like projections arising at the lateral side of pleuropodia, and the LTGs of the second to ninth abdominal segments are arranged in a row with that of the first segment. Therefore, the LTGs are structures with serial homology. The paired dorsal tracheal gills (DTGs) of the ninth abdominal segment are formed on the regions just latero-dorsal to the LTGs of this segment. Regarding the pleuropodia as the structures being homologous with thoracic legs, neither the LTGs nor DTGs are homologous with thoracic legs, but originate in the more lateral region corresponding to the future pleura of the thoracic segments. Four terminal hooks at the end of the last abdominal segment originate from two pairs of swellings on the posterior end of the embryonic eleventh abdominal segment. In conclusion, our observations reveal that both the LTGs and DTGs originate in future pleural regions. Recent embryological studies have demonstrated the subcoxal origin of insect pleura. Therefore, assuming the subcoxal nature of pleura, the LTGs and DTGs might correspond to subcoxal exites.

Quarantine Insect Species in the Russian Federation

Margarita Bush[1], Julia Lovtsova[2]

[1]All-Russian Center for Plant Quarantine, Russia, [2]All-Russian Center for Plant Quarantine, Russia

Lately, the number of countries exporting plant products into Russia has significantly increased. This has enhanced the risk of quarantine pests being introduced into the country which may have a serious economic impact. The All-Russian Plant Quarantine Center, as well as its 25 branches throughout the country, is responsible for handling pest threats. There are 39 quarantine insect species included into Russia's List of Quarantine Species. Seventeen of these species are absent in Russia and twenty two have limited distribution. The most dangerous of the introduced species are Frankliniella occidentalis (Pergande, 1895) (Thysanoptera: Thripidae), Bemisia tabaci (Gennadius, 1889) (Homoptera: Aleyrodidae) and Phthorimaea operculella (Zeller, 1873) (Lepidoptera: Gelechiidae). Currently, the range of these species is rapidly widening. One of the recent quarantine species worth mentioning is Ceratitis capitata (Wiedemann, 1824) (Diptera: Tephritidae). It was introduced into Anapa and Novorossiysk in 1994. The pest outbreak is currently expanding. In August 2011, a dangerous quarantine pest, Diabrotica virgifera virgifera Le Conte, 1868 (Coleoptera: Chrysomelidae), was detected for the first time in Rostov region. The results of laboratory tests show that F. occidentalis, Pseudaulacaspis pentagona (Targioni-Tozzetti, 1886) (Homoptera: Diaspididae) and Grapholita molesta (Busck, 1916) (Lepidoptera: Tortricidae) are the most commonly intercepted quarantine pests in imported plant products. There are also single cases of other quarantine pests being intercepted.

Remipedia ovarian characters support affinity of Crustacea and Hexapoda

Mariusz K. Jaglarz[1], Janusz Kubrakiewicz[2], Thomas M. Iliffe[3], Stefan Koenemann[4], Szczepan M. Bilinski[5]

[1]Institute of Zoology, Jagiellonian University, Poland, [2]Zoological Institute, University of Wroclaw, Poland, [3]Texas A&M University at Galveston, U.S.A., [4]Montessori-Bildungshaus Hannover, Germany, [5]Institute of Zoology, Jagiellonian University, Poland

Remipedia are rare, marine crustaceans living in anchialine caves. Their bodies combine both primitive and advanced characters and therefore the phylogenetic position of Remipedia within Crustacea remains controversial. The features of the ovary organization and ultrastructural aspects of oogenesis have been proven useful in resolving phylogenetic relationships in various arthropod groups. The structure of the female gonads in Remipedia is largely unknown. Therefore, we have examined overall morphology and ultrastructural details of the ovary in a remipede, Godzilliognomus frondosus focusing on characters relevant to phylogenetic reconstructions. The ovaries of G. frondosus are located in the anterior part of the body and are composed of a single anterior proliferative zone (the germarium), and paired posterior ovarian tubes (the vitellarium). During early oogenesis, somatic follicular cells envelope each oocyte creating distinct ovarian follicles. Throughout oogenesis, the follicular cells form a continuous but unpolarized layer on the surface of the oocyte. Because the follicles develop within the lumen of the ovarian tubes, the remipede ovaries can be classified as endogenous. Our results demonstrate that Remipedia share significant similarities in the ovary organization with Cephalocarida but also with the basal hexapod group, the Entognatha, including the subdivision of the ovary into a well defined anterior germarium and an elongated posterior vitellarium, localization of the germaria within the trunk or head region of the body, and simple, morphologically unpolarized follicular cells. Our findings give strong support for the Pancrustacea hypothesis. This work was supported by grant 2011/01/B/NZ4/00595 from the National Science Centre.

Progress on chemical utilization of cochineal insect

Hua Zheng[1], Hong Zhang[2], Liyi Ma[3], Yuanheng Guo[4], Jinyan Hu[5], Hong Zhao[6]

[1]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [2]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [3]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [4]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [5]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [6]Research Institute of Resources Insects, Chinese Academy of Forestry, China

Cochineal, the insect originated from Latin America, has been developed since its introduction to China. Its red dye, wax and other chemical substances were investigated. Most of the concerns were focused on carminic acid or carmine, the anthroquinone structural and the main component of cochineal dye. The comprehensive studies on its preparation were taken across extraction, separation, purification, drying and instrumental analysis. It was seldom used today with the traditional way of soaking directly in water for the extraction. Other physical aids such as microwave and ultrasonic wave were combined for its acceleration. To isolate carmine from protein, sugar and other impurities, adsorptive resins and enzymes were often selected for a highly purified product. Aimed to the prevention of oxidation, the extracted liquid was treated immediately by vacuum freeze drying, spray drying or other drying operations. And the dried powder could be analysed by spectrophotometry or high performance liquid chromatography (HPLC), according to different need of carmine determination with high precise or short time. Coccerin was also a natural insect wax but was not developed industrially. Its fine characteristics of whiteness, melting point, acid value and saponification value were similar to other natural bio-wax. Chitin from some cochineal species was available by usual extraction and separation, although within a low yield. It was suggested that the abundant protein and other attached constituents in the insect should be fully utilized in the future. An integrated industry of cochineal was expected to be formed in China soon.

Diurnal locomotion and feeding behaviors of rice-ear bugs measured by electrical penetration graph and video camera

Yusuke Suzuki[1], Masatoshi Hori[2]

[1]Tohoku University, Japan, [2]Tohoku University, Japan

"Pecky rice" is one of the most serious problems facing rice cultivation in Japan, causing enormous economic losses. Pecky rice is the name given to rice grains fed on by stink bugs called rice-ear bugs. Two mirid bugs, Trigonotylus caelestialium and Stenotus rubrovittatus, are among the most important rice-ear bug species. Although these 2 mirids are well studied in Japan, their daily behaviors are poorly understood. In this study, we investigated the diurnal locomotion and feeding behaviors of T. caelestialium adults by using electrical penetration graph (EPG) and video camera recordings. According to EPG recordings, feeding behavior was more common in photophase than in scotophase. The diurnal rhythms of feeding behavior were similar between mated and non-mated bugs but not between males and females, suggesting that the diurnal feeding behavior of this bug was influenced by mating experience as opposed to gender. Locomotion activity measured by a video camera was higher in photophase than in scotophase. However, the diurnal rhythms of locomotion activity were similar between males and females but not between mated and non-mated bugs, suggesting that diurnal locomotion activity was influenced by gender instead of mating experience. It is believed that this bug is active both during the day and at night, although it is more active at daytime. This study indicates that T. caelestialium is a noct-diurnal insect. In this presentation, the daily behavior of S. rubrovittatus will also be discussed.

Feeding and ovipositional behaviors of *Liriomyza huidobrensis* under lights of different wavelength

Mitsunari Sato[1], Kazuki Shibuya[2], Masatoshi Hori[3]

[1]Tohoku University, Japan, [2]Tohoku University, Japan, [3]Tohoku University, Japan

Liriomyza huidobrensis is a highly polyphagous leafminer and causes serious damage to various crops. This insect is difficult to control with insecticide sprays because its larvae develop and live within plant leaves, where they are protected from the sprays. This fly is a diurnal insect, and adults puncture plant leaves for feeding and oviposition during the day. However, the wavelengths of light that regulate their ovipositional and feeding behaviors are unknown. In this study, we investigated the feeding and ovipositional behaviors of L. huidobrensis adults under LED light of various wavelengths (355, 375, 405, 470, 530, 590, 660, and 735 nm) and in the dark and under a photoregimen of 16L:8D as controls. Flies under 355?590-nm light actively laid eggs and fed on plant leaves, as did the 16L:8D control. Feeding and ovipositional activities under 735-nm light were similar to those in the dark. It was believed that the flies recognized 735-nm light as a dark condition because they cannot sense a longer wavelength than visible red light. Although feeding and ovipositional activities under 660-nm light were lower than those under 355?590-nm light and in the 16L:8D control, the activities were higher than those in the dark and under 735-nm light. It was believed that the flies could slightly sense 660-nm LED light because it has a shorter wavelength than 660 nm. This study reveals that L. huidobrensis punctures leaves for feeding and oviposition if there are any wavelengths of light they can sense.

Application of microsatellite markers for strain identification in sterile insect techniques: *Bactrocera dorsalis* (Diptera: Tephritidae)

Siriwan Isasawin[1], Nidchaya Aketarawong[2], Sujinda Thanaphum[3]

[1]Faculty of Science, Mahidol University, Thailand, [2]Faculty of Science, Mahidol University, Thailand, [3]Faculty of Science, Mahidol University, Thailand

Bactrocera dorsalis (Hendel) or oriental fruit fly is one of the most destructive agricultural pests worldwide, causing a loss of fruit yield and constraints in the international market. In pest control programmes, sterile insect technique (SIT) involves field release of large number of mass-reared and sterile insects, resulting in successful suppression or eradication of a fruit fly population through infertile mating. Evaluation of SIT effectiveness requires efficient marking systems for distinguishing the released flies in monitoring traps. Accordingly, one SIT advancement concerns strain improvement. This study genetically characterized 11 microsatellite DNA markers in a mass-reared strain. Many of these markers were used for strain identification in field monitoring traps. The mass-reared strain was also validated in a pilot integrated pest management programme using male-only SIT in a fruit orchard, resulting in the suppression of the fruit fly population.

Structure of the female reproductive system in viviparous earwigs

Waclaw Tworzydlo[1], Agnieszka Lechowska-Liszka[2], Petr Kocarek[3], Szczepan M Bilinski[4]

[1]Jagiellonian University in Krakow, Poland, [2]Jagiellonian University, Poland, [3]University of Ostrava, Czech Republic, [4]Jagiellonian University, Poland

The vast majority of earwigs are oviparous, but in representatives of two parasitic taxa (Arixeniina and Hemimerina) the viviparity was reported. It probably represents the adaptation for parasitism, increasing the chances of nymphs to find a proper host. Here we present the analysis of female reproductive system in viviparous earwig Arixenia esau. This species has paired ovaries that are composed of 3 ovarioles attached to the lateral oviduct. The oviduct is strongly dilated and contains developing embryos, and therefore can be regarded as the uterus. The uterus wall is thick and deeply folded. The TEM analyses showed that in the individual fold, two easily recognizable layers can be distinguished. The outer zone is composed of muscle fibers, between which numerous tracheal tubes are located. The inner layer is composed of a monolayer of epithelial cells lying on a well developed basal lamina. It should be added that the basal lamina also contains tracheal branches. The epithelial cells are elongated and are of the characteristic shape. In their basal regions they are significantly folded and filled with numerous mitochondria and elements of RER. In the middle part of the epithelial cells the nuclei are located. Above the nuclei, numerous vacuoles are present. The most apical parts of these cells are equipped with microvilli that protrude into the uterus lumen. Such a unique structure of epithelial cells suggests their role in the nourishment of the embryos developing inside the uterus. The study was funded by grant 2011/01/D/NZ4/00137 from the National Science Center.

Oogenesis in a parasitic earwig *Arixenia esau*

Waclaw Tworzydlo[1], Agnieszka Lechowska-Liszka[2], Petr Kocarek[3], Szczepan M Bilinski[4]

[1]Jagiellonian University in Krakow, Poland, [2]Jagiellonian University, Poland, [3]University of Ostrava, Czech Republic, [4]Jagiellonian University, Poland

The ovaries of Arixenia esau are meroistic-polytrophic and composed of 3 short ovarioles that consist of a terminal filament, germarium and vitellarium. The ovarioles are attached to a strongly dilated lateral oviduct. In the germarium the female germline cysts are located. They are always composed of two cells only: the pro-oocyte and pro-nurse cells. The nuclei of the pro-nurse cells are large, electron-dense and contain several active nucleoli, in contrast to electron-transparent oocyte nuclei. We show that in the cytoplasm of both cells of the cyst - apart from ribosomes, mitochondria and elements of RER ? numerous small polymorphic crystalline structure are located. It should be noted as well, that both cells contain in their cytoplasm the Balbiani body (Bb) composed of numerous mitochondria. In the vitellarium, one ovarian follicle is located. It is composed of a growing oocyte and a accompanying nurse cell. The oocyte is surrounded by two-layered egg envelope and a single layer of follicular cells. On anterior pole of the oocyte, the egg envelope is characteristically folded and forms peculiar specialization with visible channels inside. The follicular cells are flattened and comprise relatively big nuclei with deeply folded nuclear envelope and several nucleoli inside. It should be noted that more numerous and more prominent invaginations of the follicular cell nuclei are located on the side facing the oocyte. Thick ovariolar sheath composed of muscle fibers and plenty of trachea surrounds the whole ovariole. The study was funded by grant 2011/01/D/NZ4/00137 from the National Science Center

Study on the correlation between the diversity of owlfly wing shape and geographical distribution

Hui Wen[1], Rui Liu[2], Li Xin Wang[3]

[1]China Agricultural University, China, [2]China Agricultural University, China, [3]China Agricultural University, China

Owlflies (Ascalaphidae) belong to Neuroptera. More than 420 species of this family were recorded all over the world. Owlflies look like Dragonfly in having developed wings and being good at fly. Ascalaphidae has three subfamilies, Albardiinae, Haplogleniinae and Ascalaphinae. Haplogleniinae distributes mainly in America and Africa. Based on the morphological study, we observed that the wing shapes of Ascalaphidae present rich diversity, especially in different geographical areas. To clarify the correlation between the diversity of wing shapes and geographical distribution, we selected 10 species from American and other 10 species from Africa, all species belong to the subfamily Haplogleniinae. The image of the forewing and the hindwing of those 20 species were obtained. The outline characters were described as closed curve by elliptic Fourier analysis (EFA). The differences of quantitative information on wing shape between the 20 species were tested with multivariate statistical analysis. The studying results show that the 20 species of Haplogleniinae present two groups based on the quantitative characters of wing outline, one group includes all 10 American species, and the other includes all 10 African species. This result indicates that the correlation between the wing shape diversity and geographical distribution is significant in the subfamily Haplogleniinae. The wing shape differences between America species and Africa species is more distinct than the wing shape differences between the species in the same continent. This conclusion needs further study with more samples.

Exploration and characterization of genes involved in the diterpene synthetic pathway for defensive secretion in nasute termite soldiers

Masaru Hojo[1], Kiyoto Maekawa[2], Seikoh Saitoh[3], Shuji Shigenobu[4], Toru Miura[5], Yoshinobu Hayashi[6], Gaku Tokuda[7], Hideaki Maekawa[8]

[1]University of the Ryukyus, Japan, [2]University of Toyama, Japan, [3]University of the Ryukyus, Japan, [4]National Institute for Basic Biology, Japan, [5]Hokkaido University, Japan, [6]Hokkaido University, Japan, [7]University of the Ryukyus, Japan, [8]University of the Ryukyus, Japan

Soldiers of the nasute termite Nasutitermes takasagoensis discharge defensive substance from frontal gland in their heads. It has been revealed that the major component of the defensive secretion is cembrene-derived polycyclic diterpene in Nasutitermes, but the synthetic pathway and the genes involved are largely unknown. To explore the genes involved in the synthesis of secretion, transcripts extracted from the cells of the frontal gland were sequenced by 454 pyrosequencing. A total of 50,290 clean sequences were assembled into 1,189 contigs that were grouped in 774 genes (isogroups). Based on sequence similarity with known proteins of other organisms, we identified four genes associated with diterpene-synthesis: 3-hydroxy-3-methyl-glutaryl coenzyme A (HMG-CoA) synthase (HMGS), HMG-CoA reductase (HMGR), farnesyl diphosphate synthase and geranylgeranyl diphosphate synthases. Assuming that the site of the defensive terpenoid synthesis strongly activates the mevalonate pathway that produces a precursor of terpenoids, two enzymes involved in the mevalonate pathway (HMGS and HMGR) were examined. Quantitative RT-PCR confirmed significantly higher expression of the HMGS and HMGR in the heads of soldiers. We then divided the head into three parts for quantitative RT-PCR and found that the expression level of HMGS and HMGR was significantly higher in a part containing the class 1 secretory cells of frontal gland. Overall, the results suggest that the mevalonate pathway of the diterpene synthesis takes place in the class 1 cells around the frontal-gland reservoir.

Evaluation of modified trunk injection method for controlling *Quadrastichus erythrinae* in Taiwan

Ting-Shuo Wang[1], Gene-Sheng Tung[2], En-Cheng Yang[3]

[1]Taiwan University, Taiwan, [2]Taiwan Forestry Research Institute, Taiwan, [3]Taiwan University, Taiwan

The gall wasp, Quadrastichus erythrinae, is an invasive alien species causing severe damage to plants of genus Erythrina in Taiwan. The Q. erythrinae spends entire larva stage in its tissues, and this characteristic makes it more difficult to kill with traditional chemical control methods. At present, trunk injection is considered as one of the most effective methods for controlling Q. erythrinae. However, the effectiveness and persistence of the insecticide applied by trunk injection on native heritage trees is still unavailable. In order to quantify the dose of injection into a tree, finding out the correlation between tree diameters and injection dose should be known first. The emergence rate of Q. erythrinae shows significant difference between imidacloprid treated group and untreated one, and no difference among those trees with diameter larger than 20 cm. Monitoring results show that damage stages drop down significantly in one month after injection. HPLC analysis shows that imidacloprid can transport to the upper layer of coral tree and reach lethal dosage in 3 weeks. Not only the evaluation of trunk injection, the methods applied in this study also provides a useful reference to control other galling phytophagous pests.

Vitellogenin cDNA Gene of Giant Water Bug (*Lethocerus indicus*)

Wijit Wisoram[1], Lertluk Ngernsiri[2]

[1]Kasetsart University, Thailand, [2]Kasetsart University, Thailand

Giant water bug; Lethocerus indicus, the native species of Southeast Asia, is one of the largest insects in the order Hemiptera, suborder Heteroptera. Here, vitellogenin (Livg) cDNA from L. indicus was cloned and sequenced. The complete full length Livg cDNA was 6048 bp long with the 5667 bp open reading frame (ORF) which encoded 1888 amino acid residues. The deduced LiVG protein contained the 18 amino acid signal peptide and several conserved motifs found in insect VGs. The LiVG amino acid sequence showed 92% identity to that of L. deyrollei and 30 - 49 % to those of other Hemipteran insect VGs available in the NCBI database. Phylogenetic tree established with vitellogenin proteins from some animals could group them as well as the classical taxonomy.

Uffda! Selling biological control to farmers in the Upper Midwest of the USA

Kelley Tilmon
South Dakota State University, U.S.A.

Importation biological control is an effective strategy for the management of introduced pests. Releases of biological control organisms such as parasitoids help these agents to become established, but these releases also provide an opportunity for outreach and education about biological control for farmers and the public. In this poster we present some lessons learned about effective biological control Extension education from our outreach efforts surrounding the release of Binodoxys communis (a parasitoid of the soybean aphid, Aphis glycines) in the upper Midwest of the USA.

Males fighting after queen removal in *Chartergellus communis* (Hymenoptera, Vespidae)

Laura Chavarria[1], Fernando Noll[2]

[1]*Universidade de Sao Paulo, Brazil,* [2]*Universidade Estadual Paulista, Brazil*

Male's behavior in tropical social wasps from the tribe Epiponini has been poorly studied, because of the difficulty to observe them inside and outside colonies. There are some observations about male's activities during the short period they spend inside colonies. Nevertheless, it is unknown what they do outside colonies and we are completely ignorant about mate behavior and sexual selection processes. For this reason, male's behavior were observed after queen removal in one colony of Chategergellus communis in Brazil. The colony was observed during five months in a farm located in Pedregulho, Sao Paulo. The day after queen elimination, males were observed outside colonies. Males fought aggressively between them, and with workers when they try to get into the nest. Workers behavior against males was similar to the defense behavior used when foreigner individuals tried to get in colonies. Observed males possibly do not belong to the colony, because in a previous study on Chartergellus golfitensis males were observed inside colonies and workers did not behave aggressively with them. Before queen removal no fights were observed between individuals, for this reason we think that males arrived to the colony, in order to try to get in and mate with virgin females. Observations of males' fights are very important because they suggest that males of social wasps compete between them to have access to females, as in other insects. Nevertheless, more studies about male's behavior are necessary to completely understand sexual selection process in social wasps.

Keywords:*social wasps, males behavior*

Reproduction level of intracytoplasmic parasitic double-strand RNA found in a Camponotus ant is related to host reproductivity

Satoshi Koyama[1], Toshiyuki Satoh[2]

[1]Tokyo University of Agriculture and Technology, Japan, [2]Tokyo University of Agriculture and Technology, Japan

Liner double-strand RNAs (dsRNA) appear to be ubiquitous in plants and fungi. The dsRNA are also seen intracytoplasmic in insects, being reported in Diptera, Lepidoptera, Orthoptera and Hymenoptera. Sizes of the dsRNA vary among taxa, and it is approximately 6.4 kbp in Hymenoptera. Up to now, the origin and function of the dsRNA is unkown. In this study, we aimed to clarify the relationship between host insect's reproductive states and the multiplication of intracytoplasmic dsRNA. We investigated arborial ants (Camponotus yamaokaii), and the multiplication level of dsRNA in each host caste was examined. Classical phenol chloroform method was applied to abstract nucleic acid. The relative amount of the dsRNA was calculated as the proportion of the amount of focal dsRNA to that of host DNA. The multiplication level of the dsRNA was related to host reproductive status. The dsRNA was significantly large in quantity in the reproductive queens, less large in the virgin queens and major workers, and poor in minor workers and males. Our results suggest that dsRNA adopt the strategy of being abundant in host with good reproductive status, usually reproductive queens, to increase their own fitness. The strategy of dsRNA can minimize extra costs of host ant colonies by avoiding self-reproduction in infertile workers occupying almost all populations in the colonies.

The effect of ATM, MRE11, RAD50, NBS1, Ku70 and Ku80 knockdown on DNA repair pathways in cultured silkworm cells

Mie Fujii[1], Hiroaki Mon[2], Masateru Takahashi[3], Hitoshi Mitsunobu[4], Jae Man Lee[5], Takahiro Kusakabe[6]

[1]Kyushu University, Japan, [2]Kyushu University, Japan, [3]KAUST, Saudi Arabia, [4]Harvard Medical School, U.S.A., [5]Kyushu University, Japan, [6]Kyushu University, Japan

Silkworm is known to be highly resistant to ionizing radiation (IR) when compared with mammals. In our previous research, it was showed that the silkworm cell line BmN4 did not undergo apoptosis after γ-ray irradiation at a dose of 100 Gy, which is sufficient to induce apoptosis in mammalian cells. Therefore, we are interested in the responses of silkworm cells against DNA double strand breaks. Double-strand breaks (DSBs) are generally dealt with by homologous recombination repair (HRR) or nonhomologous DNA-end-joining (NHEJ). In silkworm, DNA repair-related genes are highly conserved, but their functions are not well studied. In this presentation, we focused on the silkworm genes related to DSB recognition and repair, such as ATM, Ku70, Ku80, Mre11, Rad50 and NBS1. In mammals, ATM activates DSB response pathways by phosphorylating its substrates, including histone H2AX and 53BP1, which are assembled into chromatin complexes at the sites of DSBs. Human Mre11/Rad50/NBS1 complex plays an important role in the initiation of DNA strand resection required for HRR. The complex recruits ATM/Tel1 checkpoint kinase and CtIP/Ctp1 HRR factor to the DSB sites. Ku70/80 heterodimer is recruited to the DSB sites at the earliest stages of the NHEJ process. In the experiment, we constructed assay systems for HRR or NHEJ in silkworm cells. Using RNAi induced BmN4SID-1 cells, the effect of knockdown of the repair-related genes were analyzed by flowcytometer and the assay systems. Similarly, cell cycle analyses of the knockdown cells following γ-irradiation were performed.

Microbial community associated with the red palm weevil, *Rhynchophorus ferrugineus*

Bessem Chouaia[1], Matteo Montagna[2], Giuseppe Mazza[3], Sara Epis[4], Elena Crotti[5], Erica Prosdocimi[6], Violetta Vacchini[7], Daniele Daffonchio[8], Rita Cervo[9], Claudio Bandi[10]

[1]University of Milan, Italy, [2]University of Milan, Italy, [3]University of Florence, Italy, [4]University of Milan, Italy, [5]University of Milan, Italy, [6]University of Milan, Italy, [7]University of Milan, Italy, [8]University of Milan, Italy, [9]University of Florence, Italy, [10]University of Milan, Italy

The red palm weevil, Rhynchophorus ferrugineus Olivier, 1790 (Coleoptera: Curculionidae) is one of the most dangerous pest of dates, coconuts and palms. This species, originally distributed in the Southeastern Asia and Malaysia, was recently introduced in the Mediterranean Basin and is now considered a quarantine organism. The xylophagous R. ferrugineus larvae can excavate holes in the trunk of a palm trees, thereby weakening and eventually killing the host plant. The insects with unbalanced diet (i.e. phloem, blood), are usually favored by the presence of symbiotic bacteria in the gut or specialized tissues (i.e. bacteriocytes). Considering the ecology of the red palm weevil, the presence of symbionts that could help the insect development, by the degradation of cellulose or the supply of amino acids or other nutrients, is to be considered. These symbionts may offer a way to impair the reproduction and spread of the arthropods. DGGE investigation on adults, ovaries and testis showed the presence of bacteria belonging to the taxa: Acetobacteriaceae, Burkholderiales and Rhizobiales. TEM examination of ovaries, testis and fat body cells, revealed the presence of free gram-negative bacteria in the cytoplasm of the oocytes. Isolation on traditional media carried out on entire male and female adults and their guts, allowed to isolate bacteria belonging to the taxa: Enterobateriaceae, Acetobacteriaceae and Comamonadaceae. These results are confirming Acetobacteriaceae as important symbionts of arthropods with unbalanced diets. These data are now complemented by FISH microscopy and 16S pyrotag analysis.

School of Ants: Using global citizen scientist data to map urban biodiversity patterns

Andrea Lucky[1], Robert Dunn[2]

[1]University of Florida, U.S.A., [2]North Carolina State University, U.S.A.

The School of Ants project is a citizen scientist driven study mapping ants in urban areas. This public-academic partnership has two principal goals: scientific discovery and science education. Participation is open to anyone interested in contributing by following a basic collection protocol. Teachers, students, parents, kids, junior-scientists, senior citizens and enthusiasts of all stripes are involved in collecting ants in schoolyards and backyards. These samples form the basis of detailed maps of the wildlife that lives in close association with humans.

The Integrated Insect Database System of NIAES (the National Institute for Agro-Environmental Sciences, Tsukuba, Japan)

Yukinobu Nakatani[1], Hiraku Yoshitake[2], Shin-ichi Yoshimatsu[3]

[1]National Institute for Agro-Environmental Sciences, Japan, [2]National Institute for Agro-Environmental Sciences, Japan, [3]National Institute for Agro-Environmental Sciences, Japan

Insects are one of the most important components of agricultural ecosystems, and it includes many agricultural pests, benefactors, and bioindicators. Therefore, it is required that development of database system to utilize large amount of insect specimens and data, and to promote accumulation of additional ones. We have been constructing several kinds of database systems concerning insect materials, which are held in NIAES such as specimens, literature, and other data. Recently, to promote utilization of these database, we construct 'The Insect Inventory System' an integrated database system of insect resources and related data kept in the insect museum of NIAES. This system consists of two main pillars of database; one is the taxa information database which contains information accompanying with each categories of insect, spider and plant (mainly host plants of insects) taxa; another is the specimen information database which includes label data (locality, date, collector, etc.), images and DNA information. In the former taxa information database, information of each taxa are linked by interspecific relationship such as hosts, parasitoids, preys and so on. By connecting these databases, we can not only use data and images of specimens, but also various kind of information available for researches. We introduce the characteristic of the system in detail and future strategy to develop it.

Orthology prediction in a large-scale transcriptome project

Malte Petersen[1], Karen Meusemann[2], Bernhard Misof[3], Oliver Niehuis[4]

[1]Zoologisches Forschungsmuseum A. Koenig, Germany, [2]Zoologisches Forschungsmuseum A. Koenig, Germany, [3]Zoologisches Forschungsmuseum A. Koenig, Germany, [4]Zoologisches Forschungsmuseum A. Koenig, Germany

Orthology among amino acid or nucleotide sequences is a prerequisite for inferring phylogenetic relationships of the organisms from which these sequences have been sampled. However, orthology prediction is not a trivial task when working with transcriptome nucleotide data because of their inherent incompleteness. The large amount of data in transcriptome libraries can be an additional challenge for assessing orthology of sequences. Within the 1KITE project (1000 Insect Transcriptome Evolution, http://1kite.org), we assess orthology using a heavily modified version of the HaMStR pipeline (Ebersberger et al., 2009), which maps transcript sequences to pre-established orthologous amino acid sequences. The pipeline uses profile hidden Markov models (pHMMs), which allow for both rapid and specific detection of candidate orthologs, and then verifies orthology of the hits by a reciprocal search against the proteomes of reference species with a completely sequenced proteome. Here, we describe an improved mapping algorithm and its integration in the transcriptome library analysis pipeline of the 1KITE project.

Chrysomya megacephala (Fabricius) larvae: A novel bio-resource

Min Zhang[1], Chao Song[2], Guren Zhang[3]

[1]Sun Yat-sen University, China, [2]Sun Yat-sen University, China, [3]Sun Yat-sen University, China

Chrysomya megacephala (Fabricius) is usually noted for a vector of disease, a pollinator in orchards and the forensic adhibition in postmortem interval. We explored the feasibility of using C. megacephala as a novel bio-resource in the present study. Sufficient C. megacephala larvae (CML) were obtained via feeding with a variety of organic wastes. The crude oil content of dehydrated CML powder ranged from 18.1%-34.0% due to variable feeds, while the crude protein content was 45.0%-55.0%. Then, oil was pressed from a CML powder (21.2% crude oil, 54.2% crude protein), and the remained oil content and protein content in the dregs of this CML powder was found to be 4.8% and 67.7%, respectively. The oil (99.8% fat content) property was detected by gas chromatography-mass spectrometry (GC-MS). It was found that CML oil contained 30.62% oleic acid (C18:1), 21.73% linoleic acid (C18:2) and 27.30% palmitic acid (C16:0), which were the overwhelming majority in CML oil. Meanwhile, the dregs were milled into powder in which the amino acids were tested by ion exchange chromatography (IEC). The rate of essential amino acid (EAA) was 39.31%. It was concluded that C. megacephala larvae (maggots) could be used as a novel potential bio-resource for biodiesel , as well as a substitute for fish meal.

Tarsal gustatory sense in coleopteran insects

Shuhei Masuta[1], Rei Kakazu[2], Naoshi Masuoka[3], Yasuhiko Kutsuwada[4], Kazuhiro Matsuda[5], Masatoshi Hori[6]

[1]Tohoku University, Japan, [2]Tohoku University, Japan, [3]Tohoku University, Japan, [4]Tohoku University, Japan, [5]Tohoku University, Japan, [6]Tohoku University, Japan

It is well known that some insects, such as those from Orthoptera, Diptera, and Lepidoptera, use tarsi as chemosensory organs in feeding and oviposition. However, the role of the tarsus as a chemosensory organ in feeding and/or oviposition is still unclear in insects from Coleoptera, which is the largest order among living organisms. Gustatory discrimination by tarsi in coleopteran insects has yet to be proven directly in ethological experiments, although the electrophysiological and morphological properties of the tarsus have been investigated in a few coleopteran insects such as Chrysomelidae. Firstly, we investigated the existence of tarsal chemosensilla in 89 coleopteran species with a scanning electron microscope. In Chrysomelidae, all genera (species) possessed gustatory sensilla (sensilla chaetica) on their tarsi. In Cerambycidae, gustatory sensilla were observed on the tarsi in 6 of 15 species examined. Secondly, we investigated behavioral responses on tarsal gustation using Galerucella grisescens, which possess tarsal chemosensilla, and Henosepilachna vigintioctomaculata, which possess no tarsal chemosensilla. G. grisescens without maxillary palpi, labial palpi, and antennae could discriminate feeding stimulant, sucrose, in choice tests, but H. vigintioctomaculata could not. That is, G. grisescens could discriminate sucrose by only their tarsi. The insect with only tarsi could also discriminate antifeedant, brucine, and leaf surface wax of host plant. The findings are as follows: 1. In Coleoptera, tarsal gustatory sensilla may develop in only a few groups such as Chrysomeloidea, especially Chrysomelidae. 2. Chrysomelid beetles may use their tarsi as gustatory organs to discriminate their host plants.

Preparation of chitin and chitosan from the blowfly *Chrysomya megacephala*

Chao Song[1], Min Zhang[2], Guren Zhang[3]

[1]Sun Yat-sen University, China, [2]Sun Yat-sen University, China, [3]Sun Yat-sen University, China

Chitosan, a derivative of deacetylated chitin which is an important constituent of the exoskeleton of many organisms including insects, is widely used in many fields. In this work, chitin was isolated by chemical treatment from the larval cuticle of the blowfly, Chrysomya megacephala, a prevalent necrophagous species easy to be mass reared. The chitin yield (30.04%) was higher than that from traditional commercial sources such as shrimp and crab (20%-25%). The value of nitrogen content (5.78%) was lower than the theoretical value (6.89%) through elemental analysis, implying almost no protein left in this chitin product. FT-IR spectrum showed characteristic peaks of chitin and the absence of peaks at 1540 cm-1 assigned to the stretching vibration of protein, confirming that the chitin product was protein free. The deacetylation degree of chitosan derived from chitin was an average 71%. 13^C CP/MAS NMR spectroscopy revealed slight peak height differences between chitin and chitosan, as well as no peaks directing to organic impurity. The chitin structure appeared as loosely united leaves, while chitosan showed a highly porous structure by SEM analysis. These results suggested that larvae of the blowfly could be a novel alternative source for chitin and chitosan, used for many fields such as agriculture, textiles, cosmetics, medical and food processing.

Laccase2 expression involved in the specific cuticular tanning during soldier differentiation of the termite *Reticulitermes speratus*.

Yudai Masuoka[1], Satoshi Miyazaki[2], Ryota Saiki[3], Kiyoto Maekawa[4]

[1]University of Toyama, Japan, [2]University of Toyama, Japan, [3]University of Toyama, Japan, [4]University of Toyama, Japan

Termite soldiers are morphologically specialized for colony defense. The acquisition of a soldier caste is thought to have occurred just once during the course of termite evolution. Therefore, analyses on mechanisms of soldier differentiation are important for understanding the establishment of termite societies. Soldiers differentiate from workers through a presoldier stage and have well-sclerotized and pigmented cuticles. These characteristics are expected to be caused by soldier-specific mechanisms of cuticular tanning, but their origins have not been resolved. Laccase2 (Lac2) plays important roles in cuticular tanning in insects. Thus, we hypothesized that Lac2 expression was involved in soldier-specific cuticular tanning. We observed inner and outer head cuticles of each caste, and compared the Lac2 expression patterns between soldier differentiation and worker-worker molts in the termite Reticulitermes speratus. First, quantitative analyses of head cuticle colors showed that the hue changed more conspicuously during soldier differentiation than in worker-worker molts. Next, histological observations showed that exocuticules of soldier heads were significantly thicker than those of worker heads. Finally, gene expression analysis revealed that Lac2 was highly expressed just before and after molts to both soldiers and workers, and that the high expression level was kept throughout the presoldier stage. These results suggest that specific cuticular formation occurrs at the exocuticles during soldier differentiation, and that the high level of Lac2 expression during the presoldier stage is related to soldier-specific cuticular tanning. Regulatory mechanisms for Lac2 expression might be important for the acquisition of the soldier-specific cuticles.

Invasion history of the oriental fruit fly, *Bactrocera dorsalis*, in the Pacific-Asia Region: Two main invasion routes.

Xuanwu Wan[1], Yinghong Liu[2], Bin Zhang[3]

[1]Southwest University, China, [2]Southwest University, China, [3]Southwest University, China

The oriental fruit fly, Bactrocera dorsalis, was initially recorded in Taiwan Island in 1912, and has dispersed to many areas in the Pacific-Asia region over the last century. The area of origin of the species may be confidently placed in South-East China. However, routes of range expansion to new areas and underlying population processes remain partially unclear, despite having been the subject of several studies. To explore the invasion history of this species, a partition of the cox1 gene of mitochondrial DNA was used to investigate genetic diversity, haplotype phylogeny and demographic history of 35 populations, covering China and South-East Asia and including marginal populations from Pakistan and Hawaii. Based on neighbor-joining tree analysis and the distribution of haplotypes, two main invasion routes are inferred: one from South-East China to Central China, another from South-East China to South-East Asia, with both routes probably coinciding in Central China. Populations in Taiwan Island and Hainan Island might have originated in South-East China. The marginal populations in Pakistan and Hawaii might have undergone founding events or genetic bottlenecks. Possible strategies for the control of this species are proposed based on the invasion history and reconstructed expansion routes.

Genetic basis of hygienic behavior in *Apis mellifera* (Hymenoptera: Apidae): A candidate gene approach

Alejandra Scannapieco[1], Constanza Mannino[2], Maria Alejandra Parreno[3], Analia Martinez[4], Silvia Lanzavecchia[5], Maria Alejandra Palacio[6], Jorge Luis Cladera[7]

[1]INTA, Argentina, [2]INTA, Argentina, Argentina, [3]INTA, Argentina, [4]INTA, Argentina, [5]INTA, Argentina, [6]INTA, Argentina, [7]INTA, Argentina

The hygienic behavior is described as the ability of the honey bee Apis mellifera (Hymenoptera: Apidae) to detect, uncap and remove diseased brood from the hive. This behavior is performed by middle-aged workers and seems to be one of the main traits involved in the tolerance to several diseases of the hive. The variability of this quantitative trait can be explained by genetic factors but it is also strongly influenced by environmental conditions. The aim of the present study was to explore the genetic basis of hygienic behavior in honey bees by analyzing the gene expression profiles of candidate genes involved in neuronal sensitivity and olfaction. Total RNA and cDNA were obtained from the head of middle-aged hygienic and non-hygienic workers. Gene-expression profiles from each group of bees were obtained using real time quantitative PCR (RT-qPCR) targeting transcripts of AmOa1 (octopamine receptor gene), using the actin gene with a constant expression pattern as a reference. The efficiency for each locus was determined by running a standard dilution series in duplicate. The efficiency of the amplicons for each locus was adequately high and at least 97%. Transcript levels for AmOa1 showed no change between hygienic and non-hygienic bees. Together with the analysis of other candidate genes, already in progress, this result represents a first step toward the understanding of the genetic basis of hygienic behavior in A. mellifera.

Progress on Lac research: The processing and utilization

Hong Zhang[1], Hua Zheng[2], Kai Li[3], Ruguo Zhang[4], Wenwen Zhang[5], Kun Li[6]

[1]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [2]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [3]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [4]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [5]Research Institute of Resources Insects, Chinese Academy of Forestry, China, [6]Research Institute of Resources Insects, Chinese Academy of Forestry, China

This paper focused on the status quo of studies on lac processing. Besides lac resin as the main product, it was also summarized on lac red dye as co-product and shellac wax as by-product. During the past decades, techniques were in a stable situation on seed lac, shellac and lac red dye, and it was seldom developed on the producing of bleached shellac. As a traditional field with short industry chain, low conglomeration, simple and crude products, and high pollution load, the processing of lac need urgently to be a clean production with modern separation technology and non-toxic chemicals. It was also mentioned in this review on the application of lac resin for conventional industries such as foods, daily chemicals and coatings. In medicinals and pharmaceuticals, the fine availability made it becoming a new hot research topic. According to properties of the resin and requirments of its application in some specific fields, the modification methods and progressions were proposed both on physical and chemical areas. Chemically, solubility and stability of the resin can be improved by controlled deassociation or polymerization; and the swelling & disintegration velocity can be promoted by decoration with chemical reagents on active groups in the resin such as carboxyl, hydroxyl and aldehyde group. Physically, utilization range of the resin can be widened by the improvement of its film-forming property and dispersion phase. It was pointed out on the prospects of using lac dye in foods and textiles, and using shellac wax in daily chemical industry.

Reassembling the transcriptome of the whitefly *Bemisia tabaci* using Trinity

Yu-Jun Wang[1], Xiao-Wei Wang[2], Shu-sheng Liu[3]

[1]Zhejiang University,China, China, [2]Zhejiang University, China, [3]Zhejiang University,China, China

RNA-seq provides an efficient approach to analyze the transcriptome of an organism. However, reconstruction from short raw reads to full-length transcripts still presents a computational challenge, especially for species without a sequenced genome. The Mediterranean species of the whitefly (Bemisia tabaci) species complex (commonly known as Q biotype) is an important invasive pest. Its transcriptome had been sequenced and analyzed using the SOAP de novo assembly method. Recently, Grabherr et al. provided a novel transcriptome assembly method, Trinity, which could reconstruct more full-length transcripts and had higher coverage of reconstructed transcripts per locus. In this study, we reassembled the raw sequencing reads of the whitefly Mediterranean using Trinity method. A total of 181,229 sequences (mean length = 672bp) were obtained and 26,697 sequences (mean length=764bp) were annotated to NCBI non-redundant database with an E-value above 10-5, while by SOAP method, the numbers were 168,900 (mean length = 266bp) and 27,321 (mean length=539bp), respectively. After filtering the sequences that could match to SOAP constructed sequences, we got 28,735 newly discovered sequences. In addition, using Trinity we predicted 9,582 complete coding sequences (CDS) (mean length = 784bp), while the complete CDS were 3,939 (mean length = 631bp) for SOAP. We also compared the sequences assembled by the two methods, and found that more genes related to insecticide targets and metabolisms were annotated using Trinity. Reassembly and annotation of the Mediterranean transcriptome provide additional sequence resources for the functional study of the whitefly.

Study on genitalia of female cockroaches of different reproductive types

Yang LI[1], Yanli Che[2], Zongqing Wang[3]

[1]Southwest University, China, [2]Southwest University, China, [3]Southwest University, China

Six species of cockroaches belonging to three different reproductive types are examined, meanwhile external structures of female genitalia of oviparous type A, B and ovoviviparous type A are described. The results showed that cockroaches in different reproductive types have distinct differences in the external structures of female genitalia. These differences mainly are: gap between developed paraprocts of oviparous A type cockroaches is very narrow, this structure is conducive to the keel of ootheca was placed in the gap, highly sclerited first valvula is responsible for pushing eggs into ootheca, intersternal fold is opened at both sides; first valvula of oviparous type B with sclerite which is partly covering the second and third valvulae, so can help three pairs of valvulae to flip together, for three pairs of valvulae will turnover down to 90 degrees throughout gestation, intersternal fold is closed at apex only; crosspieces of ovoviviparous type A cockroaches are present and developed, first valvifer arms are highly developed to support brood sac, the whole genitalia is weakly sclerited. It is so inferred that there is a corresponding relationship among the external structures of female genitalia, oothecae and reproductive types, when one of the features known, the other two will be known.

[1]University of the Ryukyus, Japan, [2]University of the Ryukyus, Japan, [3]Tokyo Institute of Technology, Japan, [4]University of the Ryukyus, Japan, [5]The University of Sydney, Australia, [6]National Institute of Agrobiological Science, Japan, [7]Macquarie University, Australia, [8]Macquarie University, Australia, [9]University of the Ryukyus, Japan

Blattabacterium spp. are obligate intracellular bacterial symbionts present in the fat bodies of most cockroaches and a primitive termite. It has long been thought that their central role is conversion of uric acids to usable nitrogenous nutrition for their hosts. Recent publications of genome sequencing of four Blattabacterium strains have demonstrated their abilities to produce amino acids and vitamins from waste urea and ammonia, while genes related to uric acid degradation are lacking. On the other hand, two strains of Blattabacterium from xylophagous Cryptocercus punctulatus (Cpu) and a termite Mastotermes darwiniensis (MADAR) lost some genes for amino acids biosynthesis compared to the other two strains reported from omnivorous cockroaches Blattella germanica (Bge) and Periplaneta americana (BPLAN). Therefore, to examine whether the phylogenetic relationship or a feeding habit of their hosts affected evolution of a gene repertoire of the endosymbiont, we determined the genome sequence of Blattabacterium isolated from Panesthia angustipennis (Paa), which is a xylophagous cockroach but more closely related to the omnivorous cockroach B. germanica than others. The overall synteny of the Paa genome is identical to Bge and its gene repertoire is more similar to Bge, and BPLAN than Cpu or MADAR. Thus, our results suggest that evolution of Blattabacterium genome reflects their phylogenetic relationship rather than feeding habits of the hosts.

Evolution and development of bacteriome symbiosis in the Nysius seed bugs

Yu Matsuura[1], Yoshitomo Kikuchi[2], Xian-Ying Meng[3], Ryuichi Koga[4], Takema Fukatsu[5]

[1]University of Tsukuba, Japan, [2]AIST, Hokkaido, Japan, [3]AIST, Tsukuba, Japan, [4]AIST, Tsukuba, Japan, [5]AIST, Tsukuba, Japan

Insects are one of the best-studied groups of animals that have evolved intricate endosymbiosis. "Bacteriome" is a highly developed endosymbiotic organ in which an insect harbors its microbial partner in specialized cells called "bacteriocytes". For example, most taxa of the order Hemiptera whose members exclusively feed on plant sap, such as aphids and leafhoppers, possess bacteriomes, and the bacteriome-associated symbionts are essential for development and reproduction of the host insects. Meanwhile, many plant-sucking stinkbugs (Hemiptera; Heteroptera; Pentatomomorpha) are known to harbor bacterial symbionts extracellularly in the crypts of their midgut. The gut symbionts are either beneficial or essential for the host insects. However, a few genera of the family Lygaeidae (seed bugs) do not possess midgut crypts but exceptionally develop bacteriomes that harbor intracellular symbionts (Schneider 1940). Hence, it seems likely that these bug lineages might have evolved the bacteriomes de novo secondarily. The origin of the bacteriomes has been an enigma in the evolutionary and developmental biology. No study has addressed the genetic and molecular mechanisms underlying the bacteriome formation. To tackle this problem, we are studying Nysius seed bugs that possess a pair of red-pigmented bacteriomes in the abdomen. We first characterized a novel symbiont lineage associated with their bacteriomes using molecular and histological techniques. Then, we described the unique organogenesis of the bacteriomes in developing embryos, and also conducted RNAi-mediated suppression of several candidate genes during the embryogenesis. We identified a single HOX gene that is crucial for the development of the bacteriomes. [Supported by BRAIN]

Relative utility of arrhenotokous and Wolbachia-associated thelytokous *Odontosema anastrephae* figitid fruit fly parasitoids for mass rearing and biological control

Andrew Davies[1], Martin Aluja[2], John Sivinski[3]

[1]CSIRO, Australia, [2]INECOL, Mexico, [3]USDA, U.S.A.

Thelytokous parasitoid strains are theoretically advantageous when utilized for biological control, as the absence of males should reduce production costs and potentially increase field efficacy. The maternally inherited intracellular bacterium, Wolbachia pipientis, is capable of inducing reproductive alterations in parasitoids and other arthropods, including parthenogenesis induction, or thelytokous reproduction without males. We utilized indistinguishable sympatric arrhenotokous and thelytokous Odontosema anastrephae Borgmeier (Hymenoptera: Figitidae) fruit fly parasitoid strains to test the relative utility of each reproductive type for mass rearing and biological control. Multi locus sequence typing and antibiotic curing demonstrated that thelytokous O. anastrephae are singly infected with a novel Wolbachia strain likely responsible for parthenogenesis induction. Although uninfected arrhenotokous (W-) O. anastrephae display protandry, average female development time was not different between strains. Estimates of population doubling time were shorter for thelytokous Wolbachia-infected (W+) females when both strains were individually maintained, yet the reverse occurred when strains were reared in groups. This was primarily due to the significantly shorter lifespan of group-maintained W+ females, and despite W- females producing an increased proportion of male offspring when competing for hosts. For logistical reasons, mass-rearing schemes require parasitoids to be reared in groups. Therefore, we believe it is unlikely that Wolbachia-infected thelytokous O. anastrephae would be advantageous relative to uninfected arrhenotokous strains for augmentative release programs.

The use appraisal of ant feeding module

Shu-Ping Chen[1], Li-Ling Chao[2], Chung-Chi Lin[3], Yu-Der Wen[4], Su-Hua Lin[5], Wei-Lung Wang[6]

[1]National Changhua University of Education, Taiwan, [2]National Changhua University of Education, Taiwan, [3]National Changhua University of Education, Taiwan, [4]National Changhua University of Education, Taiwan, [5]National Changhua University of Education, Taiwan, [6]National Changhua University of Education, Taiwan

This study aimed to develop and explore the use appraisal of ant feeding module and to understand the benefits and satisfaction of teachers after used this module. In addition, ants' ecological teaching module integrated into the curriculum and science experiment. A total of 73 junior high, senior high and primary school teachers learn and carry out the experimental course and take a questionnaire. The methods of this study included "The use appraisal and the benefits and satisfaction of teachers used the ant feeding module". The Cronbach's α value of this questionnaire is 0.95 and all of the questions reach significantly difference ($p<0.01$). The data analysis showed that teachers felt very satisfied with the module appearance, it is an attractive design, easy to use, carry, built up, observe, and can also study ant behavior at any time. By the way, it's more important that the experiment not only can enhance a deeper impression on students, but also cause students' motive effectively. In the meanwhile, the students were more like the experimental research of ant. Therefore, it's a quite helpful module in teaching because of its excellent experimental and instructive design.

First records of new host-parasitoid associations for invasive *Dryocosmus kuriphilus* and successful establishment of parasitoid *Torymus sinensis* in central Italy

Gabriele Rondoni[1], Marco Valerio Rossi Stacconi[2], Carlo Ricci[3], Ferdinando Bin[4], Roberto Romani[5], Gianandrea Salerno[6], Petr Jansta[7], Eric Conti[8]

[1]University of Perugia, Italy, [2]University of Perugia, Italy, [3]University of Perugia, Italy, [4]University of Perugia, Italy, [5]University of Perugia, Italy, [6]University of Perugia, Italy, [7]Charles University in Prague, Czech Republic, [8]University of Perugia, Italy

The chestnut gall wasp, Dryocosmus kuriphilus Yasumatsu (Hymenoptera: Cynipidae), is native from China and is now considered the key pest of chestnut in the Countries where it has established. In Italy this species was reported for the first time in 2002. Behavioural and morphofunctional studies have been carried out focusing on antennal and ovipositor sensilla. The chestnut gall wasp induces abnormal gall formation, preventing the development of normal shoots, flowers and nuts. The attacks cause an overall weakness of the trees, which seem to become more susceptible to fungal infections. From 2007 to 2012 about 25000 galls were collected from chestnut trees in Central Italy. Overall, 15 species of hymenopteran parasitoids/hyperparasitoids, belonging to Eupelmidae, Eurytomidae, Pteromalidae and Torymidae, emerged from D. kuriphilus galls. The parasitoids Mesopolobus dubius, Torymus longicalcar, Megastigmus nigrovariegatus and Eupelmus vesicularis represent new host records. The most abundant species were Eupelmus urozonus (32% of emerged parasitoids), Mesopolobus amaenus (31%) and Torymus auratus (9%). Although these species may provide remarkable levels of parasitization (overall parasitism rates: 1%-15%) none of them effectively control D. kuriphilus populations. Therefore, in 2011 a biological control program was started in Umbria in collaboration with the Regional Phytosanitary Service and the University of Turin (Alberto Alma), by releasing Torymus sinensis, the most effective parasitoid of the chestnut gall wasp, previously released in Japan, North America and in other areas of Italy. This parasitoid has become established, as confirmed by 2012 samplings.

Development of artificial diets for rearing whitefly larvae (Hemiptera: Aleyrodidae)

Daisuke Takebayashi[1], Tsutomu Saito[2], Yosuke Tagami[3]

[1]GIFU UNIVERSITY,Japan [Shizuoka Univ.], Japan, [2]GIFU UNIVERSITY,Japan [Shizuoka Univ.], Japan, [3]GIFU UNIVERSITY,Japan [Shizuoka Univ.], Japan

An artificial diet has never been developed for whiteflies larvae. In this study, we tested efficacy of a variety of artificial diets for rearing three whitefly species, Bemisia tabaci B and Q biotypes, and Trialeurodes vaporariorum. Whitefly eggs were collected directly from the leaf surface in water, using a modified version of the Davidson's method (Davidson et al, 2000). The eggs were then isolated using a filter. Hatched eggs were used in the experiments to test the efficacy of a variety of artificial diets on larval development. Whiteflies were fed various concentrations of sucrose solution, which suitable for oviposition onto an artificial membrane, but the B biotype died at the 2nd instar stage. A classical artificial diet for the aphid (Dadd & Mittler, 1966) supported the development of B biotype until the 4th instar. With this diet, the body size at the 4th instar was similar to that when reared on a suitable plant, whereas the developmental period to the 4th instar was delayed by about 5 days, and the 4th instar eye spots never appeared. Those artificial diets were less effective for the development of T. vaporariorum and the Q biotype. In order to determine the requirements for development into adults, we measured the amino acid contents of whiteflies and their host plants using HPLC analysis. We will present the results for alternative artificial diets with modified amino acid contents based on artificial diets used for the aphid.

Characterization and expression of recombinant alpha-glucosidase III in *Apis cerana indica*

Jirattikarn Kaewmuangmoon[1], Chanpen Chanchao[2], Pakorn Winayanuwattikun[3], Atsuo Kimura[4], Kiyoshi Kimura[5], Mikio Yoshiyama[6]

[1]Faculty of Science,Chulalongkorn University, Bangkok, Thailand, [2]Faculty of Science, Chulalongkorn University, Bangkok, Thailand, [3]Faculty of Science, Chulalongkorn University, Bangkok, Thailand, [4]Graduate School of Agriculture, Hokkaido University, Sapporo, Japan, [5]National Institute of Livestock and Grassland Science (NILGS), Japan, [6]National Institute of Livestock and Grassland Science (NILGS), Japan

The α-glucosidase III (HBGase III) was found in hypopharyngeal glands of worker honeybee. This enzyme can hydrolyze sucrose in nectar to be fructose (honey). In order to find the new source of this enzyme, the recombinant technique was used to synthesize interesting enzymes. In A. mellifera (European honeybee), the full length cDNAs of α-glucosidase were cloned and characterization. In contrast, no researches on α-glucosidase were from our Thai native species. Then in this research, it aimed to focus on recombinant HBGase III from A. cerana indica due to economic honeybees. The full length of HBGase III ORF at 1,704 bp was cloned into pPICZαA (an expression vector) and was transformed into Pichia pastoris GS115 (yeast). The expression of recombinant HBGase III was induced by 1% methanol after 144 h. The obtained activity of secreted HBGase III was up to 6 U from the large scale culture (1.2 Liters). In the small scale, secreated HBGase III was purify by Histrap affinity column. Also, pH activity, pH stability, and thermal stability of the enzyme were found to be at 5.0, 4.5-7.5, and <50℃, respectively. Considering substrate specificity, the k0 value for maltose, maltotriose, maltotetraose, isomaltose, p-nitrophenyl α-D glucoside and soluble starch were estimated to be 4.53, 3.87, 2.06, 1.18, 3.33 and 0.59. Also, the Km values for these substrates were 4.5, 22.9, 26.6, 46.5, 4.4 and 11, respectively

Antibacterial activity and chemical compositions of *Apis mellifera* propolis extracts from Nan province, Thailand

Pattaraporn Boonsai[1], Chanpen Chanchao[2], Preecha Phuwapraisirisan[3]

[1]Faculty of Science,Chulalongkorn University, Bangkok, Thailand, [2]Faculty of Science, Chulalongkorn University, Bangkok, Thailand, [3]Faculty of Science, Chulalongkorn University, Bangkok, Thailand

Propolis possesses many bioactivities such as antioxidative, anti-inflammatory, anticancer, and antidiabetic activities. A lot of previous researches reported that those bioactivities of propolis depended mainly on plant sources, bee species, season, harvesting periods, and other external factors. In this research, the propolis of Apis mellifera collected from Nan province was assayed for the antibacterial activity against Staphylococcus aureus (ATCC 20651) and Escherichia coli O157: H7. The crude propolis was extracted by hexane, dichloromethane, and methanol. After that, the activity of these crude extracts were determined by agar well diffusion and microbroth dilution assay. Also, streptomycin was used as a positive control. It was shown that the crude methanol extract of propolis (CME) provided the best antibacterial activity with the minimum inhibition concentration or MIC value of 5 mg/ml and was effective to inhibit both S. aureus and E. coli. Therefore, CME was further purified by quick column chromatography. Three obtained active fractions were effective to inhibit E. coli and S. aureus with MIC values of 6.25 and 31.25 µg/ml, respectively. Later, those pooled active fractions were more purified by adsorption chromatography. These purified fraction 1A was found to be effective to inhibit E. coli with IC50 value of 0.175 µg/ml. In addition, the purified fraction 2 was effective to inhibit S. aureus with IC50 value of 0.004 µg/ml. After being analyzed by Nuclear Magnetic Resonance, it was shown that purified fraction 1A was in a cardanol group and purified fraction 2 will be analyzed in the future.

Do the promotional campaigns of firefly watching activities in Taiwan include visitor rules?

Ying-Sheue Wei
Kainan University, Taiwan

Introduction: As the vigorous development of rural tourism, the firefly watching activities are prevailing during recent decades in Taiwan. These activities provide leisure experiences as well as educational value to visitors by exhibition, watching activity, and observation. But the huge amount of visitation during the occurring season of fireflies has disturbed the mating behaviour of fireflies. Since the pro-visitation education will change the visitor behaviour during firefly watching, the study wants to investigate how the organizers promote the firefly watching activities, in order to unveil why there is improper behaviour of visitors during firefly watching. Methods: The study was conducted a survey using the content analysis. The promotion measures and the contents of the brochure, poster, e-documentation, and press release would be analysis to know if the promotional materials would include visitor rules to educate visitor before they go to watch fireflies. Results: Although the firefly watching activities are prevailing in Taiwan during April to May each year, the main organizers of these activities do not do any effort in pre-education of visitors, hence the disturbance of firefly mating and the habitat emerge in endlessly. Conclusions: Although the great mass fever of firefly watching activities would attract mass visitors during the firefly occurrence seasons, and bring huge economic benefits at the spots of the activities, the visitor behaviour should be improved. The cooperation of activities organizers and entomologist would make conditions much better.

Verification of horizontal gene transfer (HGT) of movable element, mariner-like element (MLE), among various insects and spiders inhabiting the South-West Islands of Japan.

Kaori Yamada[1], Yuichi Kawanishi[2], Seiichiro Okuma[3], Hanako Iwasaki[4], Kenji Sasaki[5], Yumiko Nakajima[6], Hideaki Maekawa[7]

[1]University of the Ryukyus, Japan, [2]University of the Ryukyus, Japan, [3]University of the Ryukyus, Japan, [4]University of the Ryukyus, Japan, [5]University of the Ryukyus, Japan, [6]University of the Ryukyus, Japan, [7]University of the Ryukyus, Japan

MLEs are derived from a kind of DNA-type transposon, "mariner", and are widely distributed in genomes of various eukaryotic organisms. Past researches have shown that these MLEs have integrated into various genomes by horizontal gene transfer (HGT). In natural population, however, an active HGT event has not been observed yet. In this study, we compared MLEs isolated from various species of Araneae (spiders), Hymenoptera and Lepidoptera in the South-West Islands of Japan. Varieties of species inhabit the narrow islands and such high density of species makes it suitable site for HGT analysis of MLEs. MLEs were isolated by the PCR amplification using five specified inverted terminal repeats (ITRs) for various known MLE types as primers. As a result, a mellifera-type MLE was found to be the major MLE type from those insects and spiders inhabiting the South-West Islands of Japan. The mellifera-type MLEs isolated from various spiders and insects were divided into two clusters (A and B) on a phylogenetic tree by Neighbor-Joining (NJ) method. The MLEs classified in cluster A showed very high homology (>92%) among them. Therefore, it is suggested that HGT of the mellifera-type MLE might occurred among those closely-inhabiting species. In addition, some clones containing a full open reading frame (ORF) encoding transposase were isolated from wasps and spiders. These ORFs showed high homology (91-96%) to that encoding functional trasnposase from Forficula auricularia. In species inhabiting the South-West Islands, the spreading and invading of the mellifera-type MLE seems to be a recent or present event.

Feeding humans with edible insects : actual state and perspectives in Belgium and Europe

Ludovic Sablon[1], Alabi Taofic[2], Christophe Blecker[3], Eric Haubruge[4], Frederic Francis[5]

[1]University of Liege - Gembloux Agro-Bio Tech, Belgium, [2]University of Liege - Gembloux Agro-Bio Tech, Belgium, [3]University of Liege - Gembloux Agro-Bio Tech, Belgium, [4]University of Liege - Gembloux Agro-Bio Tech, Belgium, [5]University of Liege - Gembloux Agro-Bio Tech, Belgium

In future decades, world population will grow up to 9 billion of people and we will be confronted to a lack of nutritive resources. We will not continue to produce proteins with our conventional livestock as beef, poultry or pig. It will therefore look to other sources and edible insects are one of these solutions. Indeed, more than 1400 species of edible insects were actually consumed by 3500 ethnic groups in the world. In undernourished populations, entomophagy is essential to relieve deficiencies in proteins, fatty acids and some vitamins. In Europe, we have acquired sedentary habits and we have lost our ancestral harvesting and hunting traditions. It is the reason of disinterest for edible insects and entomophagy was considered as a 'barbarian' food habit. Facing food challenges of tomorrow, it is important to sensitize industrialized populations and to reintroduce edible insects in our plates and habits. The first step is to overcome neophobia of food products. Our studies focused on different insect preparations and on perception of entomophagy by different age classes. Globally, our first results indicated that entomophagy was accepted by belgian consumers but the more difficult for them is to taste the first time. These results confirmed neophobia for this type of food products and thus the importance of positive informations and education for acceptance of entomophagy.

Using species distribution model to assess potential invasion risk of phytophagous pests - a case study of *Leptocybe invasa* in Taiwan

Gene-Sheng Tung[1], Chia-Chun Hsu[2], Chia-Long Huang[3], Man-Miao Yang[4]

[1]Taiwan Forestry Research Institute, Taiwan, [2]Taiwan Forestry Research Institute, Taiwan, [3]Taiwan Forestry Research Institute, Taiwan, [4]National Chung Hsing University, Taiwan

The aim of this study is using species distribution model (SDM) to model invasive phytophagous pests for early warnings and preventing possible damage in advance. An internationally important pest: Leptocybe invasa (Eulophidae) was selected for this study. The world-wide occurrences of this species were used for projecting potential distributions in Taiwan under current and two climate change scenarios (a2a and b2b at year 2050 and 2080, Worldclim database, CCCMA model). The SDM results indicated that L. invasa had a high risk of invasion under current and both climate change scenarios. The most important factors for its distribution were the lowest temperature of the coldest month (31.3%), the rainfall of the coldest season (14.8%) and isotherm (13.6%), and the western plain of Taiwan was its potential suitable habitat. The projection was done in 2009, and we recorded L. invasa in the projected area soon after year 2010, which supported this study result. This study indicated that SDM is a useful tool for assessing potential invasion risk, and provides valuable information on pest quarantine.

Optimization of fermentation conditions of mulberry wine by response surface methodology

Chu-Yan Wang[1], Jun-Qiang Jia[2], Guo-zheng Zhang[3], Xi-jie Guo[4], Zhongzheng Gui[5]

[1]Jiangsu University of Science and Technology, China, [2]Jiangsu University of Science and Technology, China, [3]Jiangsu University of Science and Technology, China, [4]Jiangsu University of Science and Technology, China, [5]Jiangsu University of Science and Technology, China

In this study, the mulberry (Morus alba L.) fruit was utilized as raw material to brew fruit wine. The effects of fermentation parameters (inoculation amount, fermentation temperature, fermentation time and pH value) on the alcoholicity of mulberry wine were investigated systematically using response surface methodology, and analyzed by the design expert 7.1 software. Based on single factor and three factor influence level tests by following the Plackett-Burman design, the optimum extraction yield was analyzed by response surface methodology (RSM). The results of RSM showed that the optimal condition for mulberry fermentation was defined as pH 3.2, inoculation amount 0.53%, fermentation temperature 31.4ºC, and fermentation time 6 d. Under this optimal condition, the alcoholicity was 12.46% (V/V).

Improved 1-Deoxynojirimycin (DNJ) production in mulberry leave fermented by microorganism

Yun-gang Jiang[1], Jun-qiang Jia[2], Xiao-ning Ma[3], Guo-zheng Zhang[4], Xi-Jie Guo[5], Zhongzheng Gui[6]

DNJ, an inhibitior of α-glucosidase, is used to suppress the elevation of postprandial hyperglycemia. In this study, we focus on screening an appropriate microorganism for performing fermentation to improve DNJ content in mulberry leaf. Results showed that Ganoderma lucidum was selected from 8 strains and shown to be the most effective in improvement of DNJ production from mulberry leave through fermentation. Based on single factor and three factor influence level tests by following the Plackett-Burman design, the optimum extraction yield was analyzed by response surface methodology (RSM). The extracted DNJ was determined by reverse-phase high performance liquid chromatograph equipped with fluorescence detector (HPLC-FD). The results of RSM showed that the optimal condition for mulberry fermentation was defined as pH 6.97, potassium nitrate content 0.81% and strain volume 2.00 ml. The extraction efficiency reached to 0.548 % in maximum which is 2.74 fold of those in mulberry leaf.

Tandem repeat markers as novel diagnostic tools for high resolution fingerprinting of *Wolbachia*

Markus Riegler[1], Inaki Iturbe-Ormaetxe[2], Megan Woolfit[3], Wolfgang J Miller[4], Scott L O'Neill[5]

[1]University of Western Sydney, Australia, [2]Monash University, Australia, [3]Monash University, Australia, [4]Medical University of Vienna, Austria, [5]Monash University, Australia

Strains of the common endosymbiotic bacterium Wolbachia pipientis are extremely diverse both genotypically and in terms of their induced phenotypes in invertebrate hosts. Despite extensive molecular characterisation of Wolbachia diversity, little is known about the actual genomic diversity within or between closely related strains that group tightly on the basis of existing gene marker systems, including Multiple Locus Sequence Typing (MLST). The genome of the wMel strain of Drosophila melanogaster contains inter- and intragenic tandem repeats that may evolve through expansion or contraction. We identified hypervariable regions in wMel, including intergenic Variable Number Tandem Repeats (VNTRs), and genes encoding ankyrin (ANK) repeat domains. We amplified these markers from 14 related Wolbachia strains belonging to supergroup A and were successful in differentiating size polymorphic alleles. Because of their tandemly repeated structure and length polymorphism, the markers can be used in a PCR-diagnostic multi locus typing approach, analogous to the Multiple Locus VNTR Analysis (MLVA) established for many other bacteria and organisms. The isolated markers are highly specific for supergroup A and not informative for other supergroups. However, in silico analysis of completed genomes from other supergroups revealed the presence of tandem repeats that are variable and could therefore be useful for typing target strains. These novel inexpensive high-throughput fingerprinting tools will be useful for studies of population genetics, horizontal transmission and experimental evolution of Wolbachia.

Study on the key technique of mass production of *Encarsia formosa* in greenhouse

Fan Zhang[1], Yingnan Wang[2], Xiaojun Guo[3]

[1]Beijing Academy of Agriculture & Forestry Scinece, China, [2]Beijing Academy of Agriculture & Forestry Scinece, China, [3]Beijing Academy of Agriculture & Forestry Scinece, China

Encarsia formosa is well known as an important parasitoid of greenhouse whithfly,and has been used successfully in many countries throughtout the world. In China, the research of production and application of Encarsia formosa has been done in control of greenhouse whithfly since 1980s. The key techniques of natural enemies mass rearing, are important for the capacity and quality of the products,which worked in building an mass production line and procedure.The study on the production and applicaition of Encarsia formosa have been studied in our institute for ten years. Some research works of Encarsia formosa production , such as host-plant selection, the whiteflies adult cleaning-up and parasitized whitefly pupae collection, were studied on the production line in greenhouse. We have primarily found the key techniques and process of mass rearing of Encarsia formosa in general greenhouse,which are significant to promote the capacity and quality of products.Also we have build a year-round quality control procedure and standard of the Encarsia formosa,to ensure the the natural enemy could be good used in the greenhouse field.

Keywords:*Encarsia formosa, Mass production, Key technique*

Improving production of toyocamycin in Streptomyces by metabolic engineering

Zheng Ma[1], Xuping Shentu[2], Yalin Bian[3], Xiaoping Yu[4]

[1]China Jiliang University, China, [2]China Jiliang University, China, [3]China Jiliang University, China, [4]China Jiliang University, China

The biopesticide has previously shown its high potential in controlling agricultural harmful pests, which was usually produced as secondary metabolites by microorganism. In our research group, a strain Streptomyces diastatochromogenes1628 capable of producing toyocamycin as a member of nucleoside antibiotics family was isolated. The inhibitory activity of toyocamycin against many pests has been proved after repeated field experiments. All the time the research progress on biosynthesis of toyocamycin was slow because of unclear molecular mechanism and metabolic pathways of toyocamycin. Therefore, it limited scale-up industrial application of toyocamycin. In order to improve the production of toyocamycin of strain 1628, we optimized and constructed the genetic transformation methods and expression system for strain 1628. The vhb gene encoding bacterial hemoglobin was successful heterologous expression in 1628, the recombinant showed the 2-fold increase in the production of toyocamycin with respect to control in primary fermentation experiment. Moreover, we constructed the gene library of strian 1628, and cloned the four key genes in gene cluster required for the biosynthesis of toyocamycin. In order to elucidate the biosynthesis and regulation mechanism of toyocamycin in microorganism at the molecular level, the function of genes or gene cluster via the genomics and transcriptomics methods will be our future work. All these will pave the way as well as supply abundant materials for future construction of engineering strain with improved toyocamycin production.

Overexpressed esterases in a fenvalerate resistant strain of the cotton bollworm, *Helicoverpa armigera*

Shuwen Wu[1], Yihua Yang[2], Guorui Yuan[3], Peter M Campbell[4], Mark G Teese[5], Robyn J Russell[6], John G Oakeshott[7], Yidong Wu[8]

[1]Plant Protection College, Nanjing Agricultural University, China, [2]Plant Protection College, Nanjing Agricultural University, China, [3]Plant Protection College, Nanjing Agricultural University, China, [4]CRISO Entomology, Australia, [5]CRISO Entomology, Australia, [6]CRISO Entomology, Australia, [7]CRISO Entomology, Australia, [8]Plant Protection College, Nanjing Agricultural University, China

Enhanced detoxification is the major mechanism responsible for pyrethroid resistance in Chinese populations of Helicoverpa armigera. Previous work has shown that enhanced oxidation contributes to resistance in the fenvalerate-selected Chinese strain, YGF. The current study provides evidence that enhanced hydrolysis by esterase isozymes also contributes to the resistance in this strain. The average esterase activity of third instar YGF larvae was 1.9-fold compared with that of a susceptible SCD strain. Much of this difference was attributed to isozymes at two zones which hydrolysed the model carboxylester substrate 1-naphthyl acetate and also a 1-naphthyl analogue of fenvalerate. A preparation enriched for enzymes migrating to one of these zones from YGF was shown to hydrolyse fenvalerate with a specific activity of about 2.9 nmol/min/mg. This material was also matched by mass spectrometry with four putative carboxylesterase genes, all of which clustered within a phylogenetic clade of secreted midgut esterases. Quantitative PCR on these four genes showed several-fold greater expression in tissues of YGF compared to SCD but no differences was found in the number of copies of the genes between the strains.

Spinosad resistance in the olive fly, *Bactrocera oleae*

Maria Eleni Gregoriou[1], Efthimia Sagri[2], Evdoxia G Kakani[3], Klelia Salpea[4], Vaggelis Harokopos[5], Frank G Zalom[6], Jiannis Ragoussis[7], Kostas D Mathiopoulos[8]

[1]University of Thessaly, Greece, [2]University of Thessaly, Greece, [3]Harvard School of Public Health, U.S.A., [4]Alexander Fleming - Biomedical Sciences Research Center, Greece, [5]Alexander Fleming - Biomedical Sciences Research Center, Greece, [6]University of California, Davis, U.S.A., [7]Alexander Fleming - Biomedical Sciences Research Center, Greece, [8]University of Thessaly, Greece

The olive fruit fly Bactrocera oleae is the most important and destructive pest of cultivated olive trees, in almost every country where olive trees grow. For the last 40 years, the management of the pest has been based on the use of organophosphate insecticides. More recently, pyrethroids and the naturalyte spinosad have been added in the arsenal against the olive fly. However, the extensive use of any insecticide inevitably leads to the development of resistance. Low level spinosad resistance to the olive fly has been demonstrated in flies caught in several California counties where the drug is the only insecticide used for the control of the fly. In Drosophila, the α6 subunit of the nicotine acetylcholine receptor (nAChR) has been implicated in spinosad resistance. On the contrary, the α6 subunit of the nAChR does not seem to be spinosad's target in Musca domestica. In order to investigate the mechanism of spinosad resistance in the olive fly, we developed a ~30-fold spinosad resistant strain in the laboratory under continuous selection. By virtue of homology we isolated B. oleae α6 nAChR both from the laboratory sensitive and resistant strains in an effort to identify possible sequence variants in this locus that could be responsible for the observed resistance. At the same time, whole transcriptome analysis was performed in heads of the sensitive and resistant strains in order to study the differential expression of the two strains and identify the loci involved in spinosad resistance.

Exploring miRNA-mRNA interactions of the honeybee embryonic development

Flavia Cristina de Paula Freitas[1], Francis de Morais Franco Nunes[2], Alexandre dos Santos Cristino[3], Zila Luz Paulino Simoes[4]

[1]University of Sao Paulo, Brazil, [2]University of Sao Paulo, Brazil, [3]The University of Queensland, Australia, [4]University of Sao Paulo, Brazil

The current knowledge about honeybee early development is mainly composed by morphological descriptions used to properly stage embryos. Only few studies investigated gene expression of some Drosophila melanogaster orthologs known as playing a role in insect development. Our group aims to describe molecular determinants governing major process of embryonic period. In particular, we herein investigated the expression of coding and non-coding transcripts in developing female embryos in order to verify their abundance and regulatory associations. Thus, we built and deep-sequenced mRNAs and small RNAs libraries for five embryonic developmental phases: clivage, blastula, gastrulation, germ-band extension and retraction, and larval body formation. Pearson correlation (r) was calculated to identify coding genes and miRNAs with antagonistic transcriptional profiles ($r < -0.8$). More than seventy thousand pairs of miRNA-mRNA showed negative correlation throughout five developmental stages analyzed. Then, we searched for miRNAs binding-sites in 3' UTR of those mRNAs using RNAhybrid software. The analysis resulted in a highly-connected regulatory network containing 318 miRNA-target interactions. The miRNAs miR-34, miR-932, miR-10, miR-92b emerged as potential regulators of neural development, since they seems to regulate expression of RhoGAP93B, puc, Rfx, esg, Tor, and ort. Our results also pointed Ikb1, which is known as a positive regulator of apoptotic process, as target of miR-263a. In Drosophila melanogaster, miR-263a donwregulates pro-apoptotic genes. Apoptosis is an important process for neurogenesis since it reduces the number of neuroblasts present in embryonic ventral nerve cord. These findings provide the first transcriptomic insights into mechanisms underlying honeybee embryogenesis.

Who rules the colony? A case study in neotropical social wasps (Hymenoptera, Vespidae: Epiponini).

Fernando Barbosa Noll[1], Carlos Alberto dos Santos[2]

[1]UNESP, Brazil, [2]UNESP, Brazil

Wasps of Epiponini tribe are polygynic and many species do not show morphological differences between 'queens' (reproductive females) and 'workers' (non-reproductive females) because castes may be determined by competitive interactions among the individuals of the colony. These conflicts may be reflected in behavioral interactions, such as those observed during egg-laying behavior. Oviposition was recorded in four colonies of Synoeca surinama (Linnaeus) and analyzed statistically. Colonies in the worker production phase showed higher rates of emergence of young and spent more time on Egg Licking and Vigilance behavior, suggesting that more conflicts were happening. The mean of time dedicated to egg-laying was of 186.97+-5.64s for all colonies and no significant difference was noted among them. In the establishment phase colonies, some workers were observed usurping queens during the Egg Licking behavior, which may be a behavior related to the reproductive control by the older workers. Our findings suggest that a subset of older workers are the real pace marker of the colony, stimulating worker behavior and policing reproduction.

Flower power? Effects of apple orchard groundcover management on arboreal spiders (Araneae)

Viktor Marko[1], Balazs Keresztes[2]

[1]*Corvinus University of Budapest, Hungary,* [2]*Georgikon Faculty for Agriculture, University of Pannonia, Hungary*

Companion plants provide alternative prey, shelter and overwintering habitat for arthropod natural enemies and thus might increase their abundance and efficacy in pest control in agricultural fields. We report results of a six-year study on the effects of annual and perennial flowering herbs sown in alleys of an apple orchard (FLOWER) on the arboreal spider communities and their prey. Plots with weed-free bare ground (BAREgr) and with regularly mowed grass (GRASS) served as controls. Altogether 4309 individuals comprising 45 species were collected in the canopy of apple trees. The abundance and diversity of spiders increased in the presence of flowering ground cover plants. The dominant spider species was Carrhotus xanthogramma (Salticidae) representing 55% of the total catch. Its abundance was 3.5 times greater in FLOWER than in BAREgr with GRASS between. Most of the other spider species showed similar pattern. When the correlation between different spider groups and their potential prey was examined, no connection was found between the abundance of apple pests [green apple aphids (Aphis spp.), apple feeding canopy insects (heteropterans, coleopterans, leafhoppers), leafminer moths and fruit injury caused by Cydia pomonella (Lepidoptera: Tortricidae) and Adoxophyes orana (Lepidoptera: Tortricidae)] and the abundance of C. xanthogramma, non-C. xanthogramma spiders and total spider community. However, the spider abundances were positively correlated with the abundance of hymenopteran parasitoids, dipterans and leafhoppers, planthoppers and froghoppers (Auchenorrhyncha). We concluded that enhancement of spiders through habitat management did not lead to increased pest suppression.

First record of deer ked (*Lipoptena cervi* (Diptera, Hippoboscidae))-infestation on the red deer in Hansag Region (Hungary)

Borisz Egri[1], Eszter Rigo[2]

[1]*University of West Hungary, Hungary,* [2]*University of West Hungary, Hungary*

Prior to our analyses we did not find any data on the deer ked infestation in the red deer in the Hansag Region(the North-West of Hungary).Between 17th November 2010 and 2nd November 2011 we examined 31 red deer all of which were shot on hunting.The aim of our observations was to declare the incidences and rates of deer ked.The investigations were carried out at the site of shooting or after the transportation of the deer, in a cold storage.They were always examined on the same region and territory of the right part of the neck (on the calves: 620,on the hinds:890 and on the stags 1440 cm²).The coats of the deer were thoroughly combed and the ked found on the animals were afterwards fixed and stored in 10% alcohol. As a result of the identification(by Soos 1995, and Kaunisto et al.,2009,with help of the Conrad USB microscopic camera(1,3 Mpix)of 1994 deer ked, the incidence of genders was found on 1113 for female and 881 for male exemplars.The quantitative parasitological data(using the QP 3.0method(Rozsa,Reiczigel et al 2000,2005))covered:the host sample size:31; the number of infected hosts in the sample:28,prevalence: 90.3%,min. intensity:1, and max. intensity:238. The confidence limits of prevalence (P=95%):0.74-0.97,mean intensity:71.21,the confidence limits of mean intensity (P=95%):48.61-102.36, median intensity: 46.5, the confidence limits of median intensity (P=95%):20-78. The index of discrepancy was: 0.551.

Termination of expression of BmEP80 protein is responsible for the lethal egg of "Ming" mutant of the silkworm, *Bombyx mori*

Qiaoling Zhao[1], Anli Chen[2], Peng Gao[3]

[1]Jiangsu University of Science and Technology, China, [2]Jiangsu University of Science and Technology, China, [3]Jiangsu University of Science and Technology, China

The l-em mutant is a lethal egg mutant from the silkworm (Bombyx mori) variety Ming. Its eggs lose water and become concaved in an hour. To study its molecular mechanism, we used SSR molecular marker technology to map the l-em gene in a region of 0.36 Mb containing 24 genes in the 10th chromosome. Fluorescence quantitative analysis of these genes showed that the expression of gene BGIBMGA006755 was reduced sharply and expression of gene BGIBMGA006756 was inhibited completely in ovarian of the mutant pupa, while the expression levels of other genes did not change between the mutant and wild type. Gene BGIBMGA006756 encodes BmEP80 protein which is a vitelline membrane protein and plays an important role in maintain the structural integrity of eggshell. Inverse PCR showed that the sequence from 3'UTR of gene BGIBMGA006755 to the forepart of gene BGIBMGA006756 was cut off and instead by new fragments which resulted in destroy of the 3'UTR of gene BGIBMGA006755, the promoter and part ORF of gene BGIBMGA006756. 2-D analysis showed that BmEP80 protein expressed from the ninth day of pupa to eclosion in wt, but no expression was detected in the mutant. The results of SiRNA interference against BGIBMGA006755 and BGIBMGA006756, respectively in pupa stage showed that expression of gene BGIBMGA006756 was reduced and the eggs became depression to some degree after SiRNA interference. Thus we speculated that the termination of expression of BmEP80 protein is responsible for the l-em mutation. *Acknowledgments The National Natural Science Foundation of China （No. 31072083）

Insect imaging at ANKA: methods, recent developments and perspective

Thomas van de Kamp[1], Tomy dos Santos Rolo[2], Patrik Vagovic[3], Alexander Riedel[4], Tilo Baumbach[5]

[1]Karlsruhe Institute of Technology (KIT), Germany, [2]Karlsruhe Institute of Technology (KIT), Germany, [3]Karlsruhe Institute of Technology (KIT), Germany, [4]State Museum of Natural History Karlsruhe, Germany, [5]Karlsruhe Institute of Technology (KIT), Germany

Non-destructive imaging techniques used to investigate the 3D morphology of biological samples include confocal laser scanning microscopy (CLSM), magnetic resonance imaging (MRI) and X-ray computed microtomography (µCT). While CLSM is restricted to transparent, fluorescent objects, MRI and µCT can be used to visualize non-translucent organisms. In µCT, X-rays emitted by a synchrotron light source provide a wide energy range, high photon flux as well as small source size and beam divergence, thus allowing analyzing even millimetre-sized samples like small insects in detail. At the ANKA synchrotron light source several studies on insect morphology were performed recently. Experiments included the investigation of the functional morphology of beetle hip joints (van de Kamp et al. 2011) and the examination of amber inclusions of fossil weevils (Riedel et al 2012). At present we are developing a fully-automated setup for high-speed tomo-graphy, including sample exchanger, on-line assessment and data-driven process control. This new system will allow a high sample throughput and facilitate even large comparative studies on insect morphology. The setup will be integrated into the IMAGE beamline that is currently being constructed. Here, we will give an overview about recent experiments and visualization techniques and provide an outlook for future developments at ANKA.

Force balance in butterfly take-off

Gaelle Bimbard[1], Dmitry Kolomenskiy[2], Richard Bomphrey[3], Simon Walker[4], Jerome Casas[5], Ramiro Godoy-Diana[6]

[1]Institut de Recherche sur la Biologie de l'Insecte, France, [2]Laboratoire de Mecanique, Modelisation et Procedes Propres, France, [3]University of Oxford, United Kingdom, [4]University of Oxford, United Kingdom, [5]Institut de Recherche sur la Biologie de l'Insecte, France, [6]Physique et Mecanique des Milieux Heterogenes, France

Up to now, take-off maneuvers remain an elusive phase of flight relatively poorly explored compared to other maneuvers, such as the forward flight or stationary flight. It is a key stage, particularly interesting since it requires a fast production of a significant amount of vertical force to counterbalance body weight and lift it up vertically. Mechanisms involved in this force production during this phase have rarely been explored. Focusing on the first downstroke, we have addressed this problem in butterflies taking-off from the ground. In order to determine if the sole aerodynamic force produced by the wings could explain the observed motion of the insect body, we have compared a rough estimate of the force produced by the wings to the acceleration of the center of mass of the insect calculated from the video tracking of the body motion. Numerical simulations were then performed to decipher the role of ground effect in take-off flight. The vertical force acting on the insect often presents a spike earlier in take-off flight, while the wing force is still at a zero value, in addition to the peak happening around the one occurring in the aerodynamic wing force. Numerical simulations highlight that ground effect cannot be responsible for it, suggesting instead a role of legs propulsion in the initiation of the maneuver.

Bumblebee venom serine protease and serine protease inhibitor affect blood coagulation and fibrinolysis

Young Moo Choo[1], Kwang Sik Lee[2], Hyung Joo Yoon[3], Yuling Qiu[4], Hu Wan[5], Mi Ri Sohn[6], Hung Dae Sohn[7], Byung Rae Jin[8]

[1]Dong-A University, Republic of Korea, [2]Dong-A University, Republic of Korea, [3]National Academy of Agricultural Science, Republic of Korea, [4]Dong-A University, Republic of Korea, [5]Dong-A University, Republic of Korea, [6]Dong-A University, Republic of Korea, [7]Dong-A University, Republic of Korea, [8]Dong-A University, Republic of Korea

Bee venom contains serine proteases and serine protease inhibitors. In this study, we identified a bumblebee (Bombus ignitus) venom Kunitz-type serine protease inhibitor (Bi-KTI) that acts as a plasmin inhibitor. Bi-KTI showed no detectable inhibitory effect on factor Xa, thrombin, or tissue plasminogen activator. In contrast, Bi-KTI strongly inhibited plasmin, indicating that it acts as an antifibrinolytic agent. The fibrin(ogen)olytic activities of B. ignitus venom serine protease (Bi-VSP) and plasmin in the presence of Bi-KTI indicate that Bi-KTI targets plasmin more specifically than Bi-VSP. These findings demonstrate a novel mechanism by which bumblebee venom affects the hemostatic system through the antifibrinolytic activity of Bi-KTI and through Bi-VSP-mediated fibrin(ogen)olytic activities, raising interest in Bi-KTI and Bi-VSP as potential clinical agents.

Bumbleee (*Bombus terrestris*) venom serine protease inhibitor acts as a plasmin inhibitor

Yuling Qiu[1], Kwang Sik Lee[2], Hyung Joo Yoon[3], Byung Rae Jin[4]

[1]Dong-A University, Republic of Korea, [2]Dong-A University, Republic of Korea, [3]National Academy of Agricultural Science, Republic of Korea, [4]Dong-A University, Republic of Korea

Bee venom is a rich source of pharmacologically active substances. In this study, we characterized a B. terrestris venom Kunitz-type serine protease inhibitor (Bt-KTI). Bt-KTI consists of two exons encoding 82-amino acids (aa), including a predicted 24-aa signal peptide and a 58-aa mature peptide. Recombinant Bt-KTI was expressed as a 6.5-kDa peptide in baculovirus-infected insect cells. Bt-KTI showed no detectable inhibitory effect on factor Xa, thrombin, or tissue plasminogen activator. In contrast, Bt-KTI strongly inhibited plasmin, indicating that it acts as a plasmin inhibitor. The electrophoretic mobility shift assay showed that Bt-KTI binds to plasmin, indicating the formation of a plasmin-Bt-KTI complex. These results demonstrate that Bt-KTI acts as an antifibrinolytic agent, suggesting a role for Bt-KTI as an anti-bleeding agent.

Molecular characterization of a spider (*Araneus ventricosus*) major ampullate silk protein

Kwang Sik Lee[1], Bo Yeon Kim[2], Doh Hoon Kim[3], Byung Rae Jin[4]

[1]Dong-A University, Republic of Korea, [2]Dong-A University, Republic of Korea, [3]Dong-A University, Republic of Korea, [4]Dong-A University, Republic of Korea

Spider silks hold great potential as biomaterials with extraordinary properties. Here we report cloning and characterization of the major ampullate silk protein gene from the spider Araneus ventricosus. A cDNA coding for the partial major ampullate silk protein (AvMaSp) was cloned from A. ventricosus. Analysis of the cDNA sequence shows that AvMaSp consists of 240 amino acids of a repetitive region and 99 amino acids of a C-terminal non-repetitive domain. The peptide motifs found in spider major ampullate silk proteins, (A)n , (GA)n, and (GGX)n, were conserved in the repetitive region of AvMaSp. Phylogenetic analysis further confirmed that AvMaSp belongs to the spider major ampullate spidroin proteins. The AvMaSp-R cDNA, which contains sequences encoding for 240 amino acids of a repetitive domain, was expressed as a 22 kDa polypeptide of soluble form in baculovirus-infected insect cells. Recombinant AvMaSp-R was degraded abruptly by trypsin. However, AvMaSp-R was stable at 100 °C for at least 30 min. Additionally, the AvMaSp-R was stable at various pH values from 2 to 12 for at least 1 h. Taken together, our findings provide the molecular structure and biochemical property for A. ventricosus major ampullate silk protein as a biomaterial.

Which between acetylcholinesterase 1 and acetylcholinesterase 2 plays the major role in synaptic transmission in the Class Insecta?

Young Ho Kim[1], Si Hyeock Lee[2]

[1]Seoul National University, Republic of Korea, [2]Seoul National University, Republic of Korea

Most insects possess two different acetylcholinesterases (AChE1 and AChE2) but it remains unknown which AChE plays the major role in synaptic transmission. To investigate the evolutionary distribution of AChE1 and AChE2, the AChE with the main catalytic function in several insect species belonging to 18 representative orders was determined by native-PAGE in conjunction with Western blotting using AChE1- and AChE2-specific antibodies. Among the 98 insect species examined, AChE1 was expressed as the main enzyme in 65 species across diverse taxa. In the remaining species, however, AChE2 was expressed as the major enzyme. These findings are contrary to the common expectation that AChE1 is major enzyme in most insects, with the exception of Cyclorrhapha, and further demonstrate that the specialization of AChE2 as the main enzyme or the replacement of AChE1 function with AChE2 function were rather common events, having multiple independent origins during insect evolution. It was hypothesized that the generation of multiple AChE2 isoforms via alternative splicing has allowed the loss of ace1during the functional replacement of AChE1 with AChE2 in Cyclorrhapha. However, the presence of AChE2 as the main AChE in higher social Hymenoptera provides an example of the functional replacement of AChE1 with AChE2 without the loss of ace1. The current findings should provide valuable insights into which AChE has evolved to perform synaptic functions and to become the main insecticide target in different species.

Availability of sugar solutions for colony development of the European bumblebee, Bombus terrestris

Hyung Joo Yoon[1], Kyeong Yong Lee[2], Mi ae Kim[3], In gyun Park[4]

[1]National Academy of Agricultural Science, RDA, Republic of Korea, [2]National Academy of Agricultural Science, RDA, Republic of Korea, [3]National Academy of Agricultural Science, RDA, Republic of Korea, [4]National Academy of Agricultural Science, RDA, Republic of Korea

Bumblebees are widely used to pollinate various crops, especially tomato, in greenhouses and fields. Here, we investigated whether different sugar solutions have any effects on the oviposition and colony development of Bombus terrestris queens. The types of sugar solution used were a white sugar solution, brown sugar solution, dark brown sugar solution, and prepared sugar solution; all solution contained with a 40% sugar concentration and 0.3% sorbic acid. Among these sugar solutions, B. terrestris queens reared on the white sugar solution exhibited the best results; the rates of oviposition, colony foundation and progeny-queen production were75.0± 11.0, 33.0 ± 9.6 and 21.7 ± 7.3, respectively, which corresponded to 1.1-33.0-fold increases over the results of other sugar solutions. Queens reared on the prepared sugar solution did not found any colonies. The death rate within one month was lowest for the queens reared on the white sugar solution at 26.1 ± 10.9%, which was 1.2?2.0-fold lower than the rate for the other sugar solutions. Furthermore, the numbers of progeny produced by queens reared on the white sugar solution, 131.4 ± 38.8 workers and 51.0 ± 40.6 queens, were also higher, corresponding to 1.1-1.2-fol d increases compared to queens raised on the other sugar solutions. Therefore, the white sugar solution was the favorable sugar solution for the egg-laying and colony developmental characteristics of B. terrestris queens.

A study on the development of functional cosmetics using silk-gland powder of silkworm

Jeong-Woo Chon[1], Haeyong Kweon[2], You-Young Jo[3], Kang-Sun Ryu[4], Heui-Sam Lee[5]

[1]National Academy of Agricultural Science, RDA, Republic of Korea, [2]National Academy of Agricultural Science, RDA, Republic of Korea, [3]National Academy of Agricultural Science, RDA, Republic of Korea, [4]National Academy of Agricultural Science, RDA, Republic of Korea, [5]National Academy of Agricultural Science, RDA, Republic of Korea

In this study, silk-gland powder of silkworm were investigated to see the possibility for functional cosmetics materials. To test possibility as a functional cosmetic materials, total content rate of amino acids, DPPH free radical scavenging assay, MTT assay, and clinical trial were done. According to the result of the analysis of the amino acids of silk-gland powder, serin (26.77%) content was the highest and asparatic acid, glycine, and glutamic acid were followed. DPPH free radical scavenging activity of silk-gland powder was lower than vitamin C by 82.3% and 97%, respectively, which is relatively good. The moisture effect were increased in twincake with silk-gland powder and baby powder with silk-gland powder compared to control cosmetics by 257.2% and 50%, respectively. Elasticity effect were increased in twincake with silk gland powder compared to control cosmetics by 181.2%. Also, baby powder with silk gland powder was classified as a practically non-irritating material based on the score 0.05 of primary irritation index. Thus, these results suggest that silk-gland powder of silkworm may have beneficial properties as a material for cosmeceuticals.

Effects of mulberry leaves as the supplements to weaning pig diet

Jeong-Woo Chon[1], Hye-Jin Kang[2], Hong-Lim Choi[3], Young-Chul Jung[4], Haeyong Kweon[5], You-Young Jo[6], Kang-Sun Ryu[7], Heui-Sam Lee[8]

[1]National Academy of Agricultural Science, RDA, Republic of Korea, [2]Seoul National University, Republic of Korea, [3]Seoul National University, Republic of Korea, [4]AT LIFE SCIENCE INC., Republic of Korea, [5]National Academy of Agricultural Science, RDA, Republic of Korea, [6]National Academy of Agricultural Science, RDA, Republic of Korea, [7]National Academy of Agricultural Science, RDA, Republic of Korea, [8]National Academy of Agricultural Science, RDA, Republic of Korea

This study was conducted to develop natural alternative antibiotics for pig production from mulberry leaves. A total 140 weaning pigs (6.66±0.4kg average body weight) were assigned to 4 treatments, 4 replicates and 9 pigs per pen in a randomized complete block design. Treatments were 1) NC (basal diet), 2) AB (basal diet+antibiotics), 3) LMB (basal diet+1% melberry leaves), and 4) HMB (basal diet+2% melberry leaves). During the whole experimental period, average daily gain (ADG) of treatment AB (602g) was higher than other treatments. However, LMB treatments was higher in feed efficiency (FE) by AB. Threfore, mulberry leaves was likely able to improve the growth performance, and reduce feed cost although they do not have similar effects like antibiotics in weaning pigs. Pigs fed with mulberry leaves (LMB and HMB) had lower total solid and volatile solid than AB. In the case of E.coli and Salmonella, the LMB inhibited their number in feces. These results suggest that the dietary mulberry leaves are likely able to improve the growth performance, occurrence of diarrhea and immune response although they do not have similar effects like antibiotics in weaning pigs.

Factors of color variations of elytra of *Harmonia axyridis*(Coleoptera: Coccinellidae)

Mi Ja Seo[1], Eun Jin Kang[2], Dae Hong Lee[3], Yong Man Yu[4], Young Nam Youn[5]

[1]*Chungnam National University, Republic of Korea,* [2]*National Academy of Agricultural Science, RDA, Republic of Korea,* [3]*Central Research Institute, Kyung-Nong, Kyungbuk, Republic of Korea,* [4]*Chungnam National University, Republic of Korea,* [5]*Chungnam National University, Republic of Korea*

Harmonia axyridis has been called the multicolored Asian ladybird beetle and showed a high level of phenotypic polymorphism in elytra color pattern within species. Up to now, there is no evidence to indicate whether the variation is genetic and/or environmental factors. Elytra color patterns of H. axyridis were classified into 5 main patterns (succinea 1, succinea 2, conspicua, spectabilis, and axyridis) according to ground color, color of marking, number of spots, and fusions between the spots. As regional results of occurrence proportions in 5 main patterns annually, succinea patterns were more collected than any other type at the rate of 90% and over. There were differences between two differential environmental condition areas on elytra color expression patterns. Specifically, it was investigated that occurrence rate of melanic patterns(conspicua, spectabilis and axyridis) relatively increased in overwintering populations collected in highly mean temperature and longer cumulative day length area. For confirming differences in their genetic constitutions of each color pattern, this study used AFLP analysis so that many segregating markers were generated among the each color pattern. Based on the sequences of colorpattern-specific AFLP markers,primers were designed for PCR amplification of genomic DNA and the AFLP markers converted into SCAR markers.

Keywords:*Harmonia axyridis, Polymorphism, AFLP*

Honeybee visiting and Nectar Characteristics on Two Species of Genus *Tilia* as a honey plant

Jingyu Han[1], Sea-Hyun Kim[2], Moon-Sup Kim[3]

[1]Korea Forest Research Institute, Republic of Korea, [2]Korea Forest Research Institute, Republic of Korea, [3]Korea Forest Research Institute, Republic of Korea

The principal objective of this study was to evaluate the efficacy of Tilia amurensis and Tilia manshurica as honey plants. Flowering period, number of flowers, honeybee wisiting, and nectar secretion were measured. The flowering period of T. amurensis was 9 days, from June 9th to June 17th, and the flowering period of T.manshurica was 11 days. from June 17th to June 27th. The estimated total number of flowers per individual tree was shown to differ by more than 6-fold between the two species T.manshurica was estimated to produce 386,000 flowers and T.amurensis was estimated to produce 63,600 flowers. Both species evidenced two peaks per day in honeybee visiting, and the total honeybee visiting scores of the two species did not differ greatly. The volume of nectar secretion, however, did differ noticeably between the two species T. amurensis secreted 3.58±0.97㎕ and T.manshurica secreted 18.4±2.01㎕.

Behavioral response of western flower thrips to visual and olfactory cues with Chrysanthemum

Yongseok Choi[1], InSoo Whang[2], JunSeok Lee[3], EunHae Han[4], YunKyu Nam[5]

[1]Chungcheongnamdo Agricultural Research & Extension Services, Republic of Korea, [2]Chungcheongnam-do Acricultural Research & Extension Services, Republic of Korea, [3]K-insect Co., Ltd, Republic of Korea, [4]K-insect Co., Ltd, Republic of Korea, [5]Chungcheongnam-do Acricultural Research & Extension Services, Republic of Korea

Behavioral responses of Frankliniella occidentalis Pergande (Thysanoptera: Thripidae) to visual and olfactory cues were assessed in a 4-way choice chamber and a Y-tube olfactometer. Frankliniella occidentalis preferred yellow flower to other color patterns (White and pink) in greenhouse. In pair wise choice test, Y-tube olfactometer test, the thrips preferred white flower to other color patterns (yellow, red, violet). But In multiple choice test, 4-way choice olfactometer test, the thrips preferred yellow color to other color patterns. Higher numbers of thirps responsed to visual and olfactory cues in chrysanthemum but visual cues higher then olfactory cues. These results suggest that color pattern is important cue for F. occidentalis.

Qualitative assessment of outbreak risk and consequences of introduction of *Bactrocera invadens* through export of fresh fruits of *Citrus sinesis* from Nigeria

Adebayo Amos Omoloye
University of Ibadan, Nigeria

The biology of Bactrocera invadens is reviewed in relation to the phytosanitary risks associated with export of fresh fruits of Citrus sinesis from Nigeria to the United States of America where the pest is not known to occur nor widely established; although other closely related fruit flies especially the Mediterranean fruit fly, Ceratitis capitata already exists. This pest, B.invadens is polyphagous and can survive in all tropical and sub-tropical conditions. It poses a potential risk to established orchards in the states of Florida, Texas and Alabama as well other states with near tropical environments. The adult pest lays eggs on fresh fruits; usually before harvest of susceptible hosts such as Ananas sativa, Mangifera indica, Psidum guajava, avocadoes and other related fruits. The emergent larvae feed and develop inside the fruit depending on the host. The consequence of introduction and entry potential through imported fresh fruits are high. The outbreak risks based on climatic conditions marching the pest etiology and host biotics as well as pest survival between crops are also rated very high. Outbreak risks can however be greatly reduced to the level meeting the phytosanitary protection of the importing country if appropriate mitigation such as quality assurance and sorting, storehouse and pre-shipment treatment with environmentally safe pyrethroids insecticide and single point mitigation by gamma irradiation at the port of exit are applied.

Occurrence and abundance of the insect pests associated with *Amaranthus* species in Ibadan Southwest Nigeria

Ismaila Adeniran Aderolu[1], Amos Adebayo Omoloye[2]

[1]*University of Ibadan, Nigeria,* [2]*University of Ibadan, Nigeria*

Survey of insects associated with the Amaranthus species was carried out in the Faculty of Agriculture and Forestry Plot beside PYTP Plot, University of Ibadan, Ibadan, Southwest Nigeria using quadrat. Three Amaranthus species: A. cruentus, A.blitum and A. hybridus were arranged in Randomized Complete Block Design and evaluated for abundance and diversity of associated insects using standard field evaluation procedures in the wet and dry seasons of 2009 and 2010. Data collected were analysed using Shannon (H) and Simpson (D) diversity indices and Evenness (E) respectively. A total of 59 insect species from 29 families and 12 orders comprising 31 defoliators, 16 minor pests, 12 predators and one (1) parasitoids were encountered on the Amaranthus species. The most abundant species in the wet season was Hymenia recurvalis (2916.8±138.83) followed by Hypolixus truncatulus (2262.7±94.10) and Lixus truncatulus (2088.7±36.37). In the dry season, similar trend occurred, Hymenia recurvalis (2311.5±32.46) followed by Clavigralla tomentosicollis (1456.3±17.77) and Lixus truncatulus (1142.3±25.58) was the most abundant species. The average species evenness (E= 0.65; 0.59) and diversity (D= 0.96; 0.96) for wet and dry seasons respectively were very high. Therefore, the most important defoliator of Amaranthus species is Hymenia recurvalis. Infestation of Amaranthus by this pest was all the year round on wild Amaranthus (Amaranthus spinosus) surveyed at the study site.

Screening and identification of resistance donor cultivar of *Amaranthus* sp. against *Hymenia recurvalis*

Ismaila Adeniran Aderolu[1], Amos Adebayo Omoloye[2]

[1]*University of Ibadan, Nigeria,* [2]*University of Ibadan, Nigeria*

Beetworm Moth (BWM), Hymenia recurvalis is a foliage feeder that causes significant yield loss of Amaranthus in Nigeria. Nine Amaranthus cultivars were evaluated for resistance against Hymenia recurvalis in the screen-house and on the field using standard procedures in the wet and dry seasons of 2009 and 2010. Also, feeding preference of the BWM for different phonological stages of Amaranthus' leaves (1 to 6weeks) was evaluated using choice and no-choice bioassays. Resistance donor cultivar of the nine Amaranthus accessions against Hymenia recurvalis infestation was evaluated. However, best four accessions were assessed for antibiosis using standard procedures. Data on leaf area damage (LARD) and number of Hymenia recurvalis per plant were collected and analyzed using ANOVA ($p < 0.05$) and descriptive statistics and thereafter rated using standard visual rating scale to identify resistant donor. The most resistant Amaranthus species to H. recurvalis was A. hybridus (LARD= 12.47 ± 0.03; 0.3insects/plant) followed by A. blitum (LARD= 19.05 ± 0.05; 0.7insects/plant).

Effectiveness of four protectants against the weevil, *Balanogastris kolae* (Coleoptera: Curculionidae) on kolantus, *Cola nitida* in storage

Kehinde Abike Kemabonta[1], Winifred Ayinke Makanjuola[2], Bukola T Sadiku[3]

[1]University of Lagos, Nigeria, [2]University of Lagos, Nigeria, [3]University of Lagos, Nigeria

Gammalin-20, though banned, is still widely used in the storage of Kolanuts in Nigeria. The effectiveness of Spintor (Spinozad), a naturally derived insecticide was compared with Gammalin- 20 and other protectants used in the storage of kolanuts against the weevil, Balanogastris kolae in Lagos and Osun States, Nigeria. Adult mortality was significantly highest in Spintor dust and Gammalin 20, higher in Alum and 'Omidun' and least in nuts treated with Phostoxin and Alum. Feeding marks, % damaged and % weight loss increased with days after treatment (DAT). The least damage was recorded at 90DAT in kolanut treated with Spintor at 2g/kg but not significantly different from treatments with Spintor (1g/kg) and Gammalin-20 (0.5ml/l). Spintor dust (1and 2g/kg) and Gammalin 20 (0.5ml/L), were relatively effective in protecting kolanuts from Balanogastris kolae infestations for 90DAT. Alum+Omidun was effective for 60DAT while Phostoxin was effective only for 30DAT but Alum+water and water (control) were not effective in the control of B. kolae infestation on kolanuts. The treatments had no effect on weight of the rats, Rattus rattus, as there was no significant difference ($p < 0.05$) between the weight of the rats fed on treated feed and the control. Histopathological tests on the liver of rats showed no disruptions in the hepatic lobes of rats fed with various treatments except on rats fed with G- 20 that had lesions in the liver. Results indicate that Spintor dust can be used as an alternative to Gammalin-20.

Effect of pollination by 3 species of pollinators, *Apis mellifera, Bombus terrestris, Osmia cornifrons* in the blueberry field

Mi-Ae KIM[1], In Gyun Park[2], Hyung Joo Yoon[3], Kyeong Yong Lee[4]

[1]RDA, National Academy of Agricultural Science, Republic of Korea, [2]RDA, National Academy of Agricultural Science, Republic of Korea, [3]National Academy of Agricultural Science, RDA, Republic of Korea, [4]RDA, National Academy of Agricultural Science, Republic of Korea

To improvement quality of the blueberry fruit, 3 species of bee, Bombus terrestris, Apis mellifera and Osmia cornifrons were used for pollination in blueberry field in Pyeongtaek province. This study was also conducted using 3 kinds of methods for pollination effect, natural condition, net-house and control method. Blooming time of blueberry shows always during the May, foraging behavior of bees used in this examination showed different tendency each other. Especially pollinating time of B. terrestris was 2.77sec and transfer time between flower was 2.29sec. Rate of blueberry fruit setting pollinated with B. terrestris, A. mellifera, O. cornifrons were showed 87.7%, 89.6%, 66.5% respectively. And, rate of fruit setting of the untreated control and the control(natural condition pollination) were 15.4% and 80.3%. Quality of fruit pollinated with B. terrestris and A. mellifera showed higher than O. cornifrons in natural field condition in fruit weight. And, the rate of blueberry fruit setting pollinated with B. terrestris, A. mellifera, O. cornifrons were showed 87.7%, 89.6%, 66.5% respectively. And, rate of fruit setting of the untreated control and the control(natural condition pollination) were 15.4% and 80.3%. The rate of productivity increase obtained using the B. terrestris was 9%~17% greater than that obtained using natural pollination.

An ecotoxicoproteomic approach (SELDI-TOF MS) to mixture toxicity of trace metals on eggs of mayfly, *Ephemera orientalis* (Ephemeridae, Ephemeroptera)

Hyoung-ho Mo[1], Yongeun Kim[2], Myung-seob Kim[3], Yun-sik Lee[4], Sung-Eun Lee[5], Key-Il Shin[6], Kijong Cho[7]

[1]Korea University, Republic of Korea, [2]Korea University, Republic of Korea, [3]Korea University, Republic of Korea, [4]Korea University, Republic of Korea, [5]NANOtox Tech , Republic of Korea, [6]Hanguk University of Foreign Studies, Republic of Korea, [7]Korea University, Republic of Korea

Proteomics provide potential in the discovery of new sensitive biomarkers for environmental pollution. We utilized SELDI-TOF MS (surface enhanced laser desorption/ionization time-of-flight mass spectrometry) to analyze the proteomic profile of mayfly eggs (Ephemera orientalis) exposed to triple mixture of trace metals (lead, mercury and copper). In the previous experiment the HC10s (10% egg hatching inhibiting concentration) of each trace metal were determined by 2 week egg hatching test. In the three-component-mixture test, each metal ranged 1/6 to 1 of HC10, and the mixture design was augmenting simplex-lattice design. The protein peak patterns of E. orientalis eggs exposed to triple mixtures of trace metals were analyzed and compared using ProteinChip® Data Manager software (version 3.0, Bio-Rad, USA). This work could be the basics to develop the novel biomarker for aquatic ecological monitoring.

Quantification and varietal variation of anthocyanin pigments, free sugars and fatty acids in mulberry fruits (*Morus alba* L.)

Hyun-bok Kim[1], Sun-lim Kim[2], Gyoo-byung Sung[3]

[1]National Academy of Agriculture Science, Republic of Korea, [2]National Institute of Crop Science, Rural Development Administration, Republic of Korea, [3]National Academy of Agriculture Science, Rural Development Administration, Republic of Korea

This study was carried out to evaluate the components and content of anthocyanin pigments, free sugars, and fatty acids in mulberry fruits. The first, cyanidin-3-glucoside (C3G) of anthocyanin pigments in the mulberry fruits was separated and quantified by HPLC system using a Nova-Pack C18 column. Among the 38 tested accessions, one variety and thirty-four strains showed only C3G peak with 0.57 ~ 1.15 % contents, whereas C3G pigment was not detected in three accessions. The second, fructose and glucose were identified as the major free sugars. However, sucrose and maltose were not detected in this study. The mean contents of fructose and glucose were 4.49 ± 1.06 % DW, 4.62 ± 1.08 % DW, respectively. The third, palmitic acid, stearic acid, oleic acid and linoleic acid were detected as a major fatty acid in mulberry seed. Their rates of composition were 8.8±3.3, 4.2±1.6, 5.8±2.3, and 81.2±6.9(%), respectively. The unsaturated fatty acids such as oleic acid and linoleic acid were abundant in mulberry seed. From the above results, we conformed that mulberry fruits are of great value as functional food resources as well as fruits themselves of crop increasing income for farmers.

Effects of diamondback moth resistant transgenic cabbage (*Brassica oleracea*) on arthropod community structure

Young-Joong Kim[1], Ki Jung Nam[2], Soon-Chun Jeong[3], Chee Hark Harn[4], Chang-Gi Kim[5]

[1]Korea Research Institute of bioscience & Biotechnology, Republic of Korea, [2]Korea Research Institute of bioscience & Biotechnology, Republic of Korea, [3]Korea Research Institute of bioscience & Biotechnology, Republic of Korea, [4]NongwooBio Co., Ltd., Republic of Korea, [5]Korea Research Institute of bioscience & Biotechnology, Republic of Korea

The insect resistant transgenic crops may have an adverse effect on ecosystems because they may affect not only target species but also non-target species. We assessed the effects of diamondback moth resistant transgenic cabbage (Brassica oleracea) expressing insecticidal Cry1Ac toxin on arthropod community structure. The arthropod species on two transgenic cabbage lines (C-24 and C-30) and parental non-transgenic line (AD-126) were monitored in an isolated field located in Cheongwon in South Korea every week from 3 June to 15 July in 2011. We compared the structures of arthropod community using NMDS (non-metric multidimensional scaling) and ANOSIM (analysis of similarities). Although we found that abundance of Plutella xylostella was significantly different among cabbage lines, the result from NMDS and ANOSIM showed that there was no significant difference in arthropod community structures between transgenic lines of cabbage.

Fine structural analysis on the spinning nozzles for the viscid silks in the spider *Nephila clavata* (Araneae: Nephilidae)

Myung-Jin Moon[1], Hoon Kim[2], Hyo-Jung Kim[3], Jong-Gu Park[4]

[1]Dankook University, Republic of Korea, [2]Dankook University, Republic of Korea, [3]Dankook University, Republic of Korea, [4]Dankook University, Republic of Korea

The fine structural characteristics of the spinning nozzles for capture thread production in the golden orb-web spider Nephila clavata were analyzed using scanning and transmission electron microscopes. Sticky and gluey capture threads of the web are originated from the silks of a pair of flagelliform glands and two pairs of aggregate glands. They supply precursors of the secretory silks to a pair of characteristic 'triad' spinning units on the posterior spinnerets. The aggregate gland is composed of large and multi-lobed secretory region and thick excretory duct surrounded by large irregular nodules. The nodules contain numerous mitochondria and glycogen particles within their cytoplasm and they are surrounded by the same sheath of thin connective tissue. The excretory duct of this gland basically consists of three superposed types of cells which are inner columnar epithelium, nodule forming cells and outer connectives. Secretory region of the aggregate gland which produces water-soluble components of the capture thread comprises discrete secretory vesicles and extensive rough endoplasmic reticulum.

Microstructural analysis of the mouthparts in the bark beetle *Ips acuminatus*, and their implication as external carriers of pathogens

Myung-Jin Moon[1], Jong-Gu Park[2], Won-Ill Choi[3]

[1]Dankook University, Republic of Korea, [2]Dankook University, Republic of Korea, [3]Korea Forest Research Institute, Republic of Korea

The bark beetle Ips acuminatus Gyllenhal (Coleoptera: Curculionidae: Scolytinae) has been reported as a common group of bark beetle that infest and damage pine and spruce trees. These beetles are mostly plant feeders and are economically important pests of crops. Since the adult beetles chew the sapwood to create tunnels called galleries, they have developed effective drilling mouthparts enough to make galleries directly into the heartwood of the tree. The mouthparts of this bark beetle exhibit typical morphology of mycophagous coleopteran beetles and have those characteristics of chewing mouthparts that can excavate galleries in the hardwood. Here, we have analysed the fine structural aspects of its functional mouthpart using the field emission scanning electron microscopy (FESEM) for the purpose of understanding the mechano-dynamic characteristics and further biomimetic approaches. In addition, we also demonstrate their implication ability to act as external carriers of pathogens as a part of research for controlling this pest animal.

Two generations of the European corn borer in Slovakia

Ludovit Cagan[1], Miroslav Pernis[2], Andrea Cerevkova[3]

[1]Slovak Agricultural University in Nitra, Slovakia, [2]Slovak Agricultural University in Nitra, Slovakia, [3]Institute of parasitology SAS, Kosice, Slovakia

European corn borer (Ostrinia nubilalis) population in Gab?ikovo (47°53´59´´N; 17°37´6´´E), Slovakia, was examined for the incidence of its second generation in 2010. The first egg clusters of the second generation were found on maize leaves on August 23 with consecutive ear damage firsty found on September 3. At the beginning of October, more than 50 % of the maize plants were infected by the larvae of the second generation. On October 7, together 660 larvae were collected from the maize cobs to record their developmental stage. Climatic conditions in 2005-2010 are discussed and compared with climatic conditions in 1990´s when, for the first time, a partial second generation occurred in Slovakia. The results show that degree-days accumulation (base 10°C) from the beginning of the year to the date of the first egg clusters in June and for the whole year did not influence the development of the second generation. Higher temperatures in the period from the beginning of July to the end of October in 2005-2010 seem to be responsible for the development of the second generation. Furthermore, changing climatic conditions (high temperatures in summer and autumn) probably led to the shift of bivoltine population northwards to historically univoltine habitats.

A novel mosquito feeding system for routine blood-feeding

Deng Lu[1], Koou Sin Ying[2], Png Ah Bah[3], Ng Lee Chin[4], Sai Gek Lam[5]

[1]National Environment Agency, Singapore, [2]National Environment Agency, WHO collaborating centre for arboviruses and their associated vectors, Singapore, [3]National Environment Agency, WHO collaborating centre for arboviruses and their associated vectors, Singapore, [4]National Environment Agency, WHO collaborating centre for arboviruses and their associated vectors, Singapore, [5]National Environment Agency, WHO collaborating centre for arboviruses and their associated vectors, Singapore

Vector-borne disease research often requires maintenance of laboratory colonies of vectors. Blood feeding of mosquitoes is thus required for the maintenance of these colonies. Due to the increasing awareness on animal welfare and stringency in regulations governing the scientific use of animals for research, coupled with the inconvenience of using live animals as blood hosts, we developed a simple and user friendly blood feeding system for artificial feeding the mosquitoes The system consisted of a collagen membrane casing filled with specific pathogen free (SPF) mini-pig blood, which is warmed by a simple in-house designed heating device. Blood feeding rate, fecundity, survival rate and hatchability of Ae. aegypti and Ae. albopictus colonies maintained by the feeding system were compared with those raised by conventional guinea pig feeding method. Aedes aegypti, displayed a significant difference in the feeding rate when offered blood meal using the membrane feeding (85.3%) and the guinea pig feeding (96.2%) methods (P=0.012). Though the feeding rate was reduced, the level was acceptable for maintenance of laboratory colonies. There was no significant difference in the fecundity (P=0.556), survival rate (P=0.715), and hatchability (P=0.932) between the two methods. For Ae. albopictus, the two feeding methods yielded no significant difference for the three parameters (fecundity, survival rate and hatchability=0.887, 0.580 and 0.564, respectively). Hence, we conclude that this simple collagen based membrane blood feeding system can be used for routine colonization of laboratory strains of Ae. aegypti and Ae. albopictus.

Dispersal patterns of pine wilt disease at the newly infested areas

Yoo Jeong Choo[1], Dong-Soo Kim[2], Yeong-Jin Chung[3], Young-Seuk Park[4]

[1]Kyung Hee University, Republic of Korea, [2]Kyung Hee University, Republic of Korea, [3]Kyung Hee University, Republic of Korea, [4]Kyung Hee University, Republic of Korea

Pine wilt disease (PWD) caused by the pine wood nematode (PWN), Bursaphelenchus xylophilus, is a serious pest for pine trees in many countries including South Korea, Japan, China, Taiwan and Portugal. The Japanese pine sawyer and long-horned beetle, M. saltuarius, are vectors of PWN in South Korea, causing the disease dispersal. In Korea, after the first occurrence of PWD in Busan in 1988, PWN had expanded its infestation areas in Korean nationwide scale. Better understanding on the dispersal patterns of the disease is essential for installing the control strategy of PWD. In this study, we evaluated the dispersal patterns of PWD at the newly infested areas using data monitored from 1998-2004. Both area and the number of patches (infested area), dispersal patterns, and dispersal distance were measured at two different spatial scales (stand and region) using ArcGIS. We defined four different dispersal types in patches: the similar patch shape with the previous year, movement of patches, dispersal only one direction, and dispersal of multiple directions. The areas and the number of patches infested were increased as a function of year after the first infestation. Annual dispersal distance increased with the time progress. Maximum dispersal distance in each year increased, while minimum dispersal distance decreased, resulting from increase of the number of patched infested by PWN. We discussed the efficiency of control activities for different dispersal patterns at the nearly infested areas.

Comparative genomic analysis of the UDP-glycosyltransferase multigene family in insects

Seung-Joon Ahn[1], Heiko Vogel[2], David Heckel[3]

[1]National Institute of Horticultural and Herbal Science, Republic of Korea, [2]Max Planck Institute for Chemical Ecology, Germany, [3]Max Planck Institute for Chemical Ecology, Germany

UDP-glycosyltransferases (UGT) catalyze the conjugation of a range of diverse small lipophilic compounds with sugars to produce glycosides, playing an important role in the detoxification of xenobiotics and in the regulation of endobiotics in insects. Recent progress in genome sequencing has enabled an assessment of the extent of the UGT multigene family in insects. Here we report over 310 putative UGT genes identified from genomic databases of ten different insect species including four lepidopteran species. Phylogenetic analysis of the insect UGTs showed Order-specific gene diversification and inter-species conservation of this multigene family. Only one family (UGT50) is found in all insect species surveyed (except the pea aphid) and may be homologous to mammalian UGT8. Three families (UGT31, UGT32, and UGT305) related to Lepidopteran UGTs are unique to baculoviruses. A lepidopteran sub-tree constructed with 40 H. armigera UGTs and 44 Bombyx mori UGTs revealed that lineage-specific expansions of some families in both species appear to be driven by diversification in the N-terminal substrate binding domain, increasing the range of compounds that could be detoxified or regulated by glycosylation. Many UGTs were expressed in fat body, midgut, and Malpighian tubules, consistent with functions in detoxification, and some were expressed in antennae, suggesting a role in pheromone deactivation. These findings from this comparative study of two lepidopteran UGTs as well as other insects reveal a diversity of this gene family and show the magnitude of the task ahead, to determine biochemical function and physiological relevance of each UGT enzyme.

OCH-group (Odonata-Coleoptera-Hemiptera-group), the representative aquatic insect group in the Upo Wetland, Korea

Jun Shik Bae[1], Dong Gun Kim[2], Cha Young Lee[3], Jeong Mi Hwang[4]

[1]Daejin High School, Seoul, Republic of Korea, [2]Korea University, Republic of Korea, [3]Korea University, Republic of Korea, [4]Korea University, Republic of Korea

The Upo Wetland is the largest riverine wetland in Korea. It was formed about 1 million years ago by the flooding effect of the Nakdong River. This study aimed at an investigation of representative aquatic insect group in the wetland. Field survey was conducted in the spring of 2012, and related literatures on Korean wetland fauna were reviewed. Hand nets were used to collect aquatic insects and other benthic macroinvertebrates. Collected specimens were identified in the laboratory using available key books and references. As a result, 135 species, 105 genera, 59 families, 16 orders, 7 classes, and 3 phyla of benthic macroinvertebrates were identified in the whole area of the Upo Wetland. The Odonata-Coleoptera-Hemiptera-group (OCH-group) was known to be the representative aquatic insect group in the Upo Wetland. It showed > 50% of total species richness, even higher than that of non-Insecta group (33.75%). As analyzed with other reference wetlands in Korea, the OCH-group was shown to be the representative wetland aquatic insect group demonstrating > 50% of whole benthic macroinvertibrate communities (Deokso 57.6%, Mungyeong 66.7%, Dunchon 61.5%, Jingwannae-dong 66.7%, and Gokseong 58.6% wetlands). On the other hand, the OCH-group composition of the Topyeong Stream (29.7%), a lotic section of the Upo Wetland, Gapyeong Stream (2.8%), a typical mountain stream in Korea, and Andong Lake (19.6%), a large dam-lake in Korea, were relatively low. From this result, it is suggested that the OCH-group composition is the key characteristics in determining habitat conditions of wetland ecosystems in Korea.

Studies on taxonomy, bology and pest status of Indian biotypes of *Acanthoscelides macrophthalmus*(schaeffer) (Coleoptera : Bruchidae)

Desh Raj Thakur

Himachal Pradesh University, Shimla, India

A large number of non-native insect species invading new areas either accidentally or through man mediated trading consignments. Similarly many pulse beetles (bruchids) have crossed the geographical boundaries and becoming cosmopolitan in distribution through human-mediated migrations or accidently, thus posing major pest problem worldwide particularly in the absence of their natural enemies. A leucaena bruchid beetle, Acanthoscelides macrophthalmus (Schaeffer) (Coleoptera: Bruchidae) native to Central and Southern America has somehow crossed the geographical boundaries and widely spread in different states of the India and found infesting seeds of Leucaena leucocephala (Lamark) de Wit plant almost throughout the subcontinent. Acanthoscelides Schilsky (1905) is one of the largest genus of the tribe Acanthoscelidini containing more than 340 species globally and the species, macrophthalmus was described by Schaeffer in 1907 and placed under genus Bruchus but Johnson in 1968 rightly put the species under genus Acanthoscelides. The congeneric species, A. pallidipennis reported from China, Korea and Japan and A. obtectus (Say) has been recently reported from India. Studies of Indian bruchids carried out so far did not reveal the complete taxonomy, biology and pest status of this species except a mere reference of its presence from the pods of Albizia lebbeck (L.) Benth from southern part of the country. However, phyotosanitary risk of thirteen bruchid species in legumes bulk imports has been alarmed by National Quarantine Division (NQD) and hidden infestation instances of different species belonging to Acanthoscelides, Bruchidius and Caryedon genera and their X-ray screening immediately on arrival in Indian Territory was advocated.

Plant-based insect repellent: is that an appropriate strategy to malaria burden in Ethiopia

Karunamoorthi Kaliyaperumal[1], Argaw Ambelu[2], Esayas Alemayehu[3]

[1]Jimma University, Ethiopia, [2]Jimma University, Ethiopia, [3]Jimma University, Ethiopia

Malaria is a major public health issue in the tropical and sub-tropical countries of the world, particularly in Ethiopia. The majority of the malarial victims are the adults who live in the resource-constrained remote areas, children and the expectant mother. Personal protection measures are the key interventions to prevent arthropod-borne diseases in order to reduce the disease transmission. Although insecticide treated nets (ITNs) and indoor residual spraying (IRS) are effective in minimizing the vector-borne disease burden, it may not be effective when the malaria vectors are exophilic and exophagic. Furthermore, in East Africa particularly in Ethiopia, Anopheles gambiae complex's biting activity tends to start in the early evening hours. In this view point, repellents could play the pivotal role. However synthetic repellents are expensive, can cause allergic reactions and a few of them require electricity. In this context, plant-based insect repellents could be extremely useful and helpful. Although usage of plant-based insect repellents is a part of the Ethiopian tradition and culture, there are many issues which need to be addressed to minimize the malaria burden in Ethiopia. Even though plant-based insect repellents cannot be employed as a frontline vector control tool, it could serve as an appropriate/supplementary tool in combination with the existing malaria control interventions like ITNs and IRS.

Morphometrics and aspects of Bio-ecology of *Ephestia cautella* (Lepidoptera : Pyralidae) on stored date fruit (*Phoenix dactylifera*) and hermetic control technique

Kehinde Olajide Kabir Popoola[1], Jafar Braimah[2]

[1]*University of Ibadan, Nigeria,* [2]*University of Ibadan, Nigeria*

Rate of fecundity, life cycle, morphometic characteristics of Ephestia cautella and control were investigated. These were done on sterilized dried date (Phoenix dactylifera) as substrate. Daily fecundity of 17 eggs was recorded, while a total of 1117 eggs were laid by 15 adults female E.cautella within 6 days of oviposition in perforated date. The life cycle from egg to adult took 37 ± 1.92 days, under a temperature and relative humidity of 32.5 ± 1 0C and 70 ± 5% respectively. First filial generation (F1) of 1, 217 adults emerged after 30 days of life cycle study, with sex percentage ratio of 54.7%: 45.3%, males and females respectively. The morphometric characteristics of E.cautella revealed that female and male adult mean total body length ranges between 8.2 - 10.0 mm and 7.9 - 8.9 mm respectively. The control set up on larval stage using varied polythen bag layers of three, two, and one layer with thickness of 0.056mm for hermitic control treatment confirmed that three bags layers was the best treatment. Recorded percentage mortality values of 74.20%, 19.36% and 0.26% were obtained respectively from the set up.

Effects of gibberellic acid (GA3) on hemocyte numbers, morphology and mitotic indices of *Galleria mellonella* L. (Lepidoptera: Pyralidae)

Hülya Altuntaş[1], Fevzi UÇKAN[2], Yavuz Ali Kilic[3], Ekrem ERGİN[4]

[1]Anadolu University, Turkey, [2]Kocaeli University, Turkey, [3]Anadolu University, Turkey, [4]Gülhane Military Medical Academy, Nursing School, Turkey

The impacts of different doses of the plant growth regulator, gibberellic acid (GA3) in diet on the number of total and differential hemocytes, and mitotic indices were investigated using Galleria mellonella L. (Lepidoptera: Pyralidae) larvae. To investigate the effects of different doses of GA3 (50 to 5,000 ppm) on the number of circulating hemocytes, last instars were used and hemolymph suspension diluted in anticoagulant solution were applied to an improved Neubauer Hemocytometer. Different and mitotic hemocyte counts were assayed by Giemsa dye method. Total (THC) and differential hemocyte counts (DHC) were assayed under a Leica DM6000 B microscope with bright field and phase contrast optics. Exposure of G. mellonella to a diet containing GA3 resulted in a remarkable increase in the number of circulating hemocytes at doses <1,000 ppm with respect to untreated larvae whereas GA3 application had no effect on the number of different hemocyte types. The percentage of mitotic index also increased at 5,000 ppm. We suggest that lower doses of GA3 may induce hormesis effect that is characterized as low dose stimulation of potentially toxic substances at sublethal concentrations. Consequently, increasing amount of GA3 in diet of larvae negatively influenced the cellular immune defence of insects.

Determination of diazinon residues in grape and sour grape

Khalil Talebi[1], Ehsan Torabi[2]

[1]University of Tehran, Iran, [2]University of Tehran, Iran

Organophosphorous, markably diazinon, are still used extensively in vineyards in Iran in order to suppress pests such as the European grapevine moth (Lobesia botrana). Considering the fact that grape is mostly consumed fresh in Iran and verjuce, a product which is made from fresh unripe green grapes (sour grapes), is widely used in oriental cuisine specially in Persian cooking. Residue of this pesticide in table grapes and sour grapes can pose harmful effects on the consumer's health. The residues and dissipation pattern of diazinon on grape and sour grape was studied under field conditions. Diazinon was applied to a local vineyard variety at recommended dose (600 mg a.i.L-1) with three intervals. Representative samples were taken at 0, 1, 2, 5, 8 and 12 days after the second spray (sour grape stage) and up to 32 days after the last spray (grape stage). Extraction was done by shaking the homogenized samples with a mixture of methanol: acetonitrile:deionized water (1:1:1 v/v/v). Solid phase extraction was used for clean up and quantification analysis of the residues was done using a gas chromatograph apparatus equipped with NPD detector. Results revealed dissipation of diazinon in sour grape and grape followed first-order kinetic and the equations were C0= 4.4631e-0.46t and 8.5844e-0.21t with half lives of 1.5 and 3.3 days respectively. Diazinon residues in sour grape and grape reached below the Maximum Residue Level (MRL) of 0.5 mg.kg-1 after 5 and 15 days respectively.

Larvicidal activity of essential oils from *Thymus kotschyanus* and *Mentha longifolia* against *Tribolium castaneum*

Hoda Akrami[1], Saeid Moharramipour[2]

[1]*Science and Research Branch, Islamic Azad University, Tehran, Iran,* [2]*Tarbiat Modares University, Tehran, Iran*

This study was conducted to establish the larvicidal activity of essential oils from Thymus kotschyanus Boiss and Hohen and Mentha longifolia L. against one-day old larvae (one DOL) and 10-days old larvae (10 DOL) of Tribolium castaneum (Herbst). The flowering dried parts of the plants hydrodistillated by a clevenger-type apparatus for 3 h. Different concentrations from 415.38 to 723.08 µL/L air of T. kotschyanus and from 0.6 to 1.6 µL/L air of M. longifolia were used against one DOL and the concentrations from 400 to 784.62 µL/L air of T. kotschyanus and from 0.3 to 1.3 µL/L air of M. longifolia were used against 10 DOL to determine the larvicidal activity of the essential oils. After 24 hours from commencement of exposure, larval mortality was recorded. Experiment was carried out at 26±1 C°, 65±5 RH% in dark condition and in five replications with 20 larvae in each replication. Data were analyzed by Probit analysis using the SAS program. LC50 values of the T. kotschyanus and M. longifolia were 543.49 and 10.15 µL/L air against one DOL, and 580.70 and 15.28 µL/L air respectively against 10 DOL of T. castaneum. The results show that M. longifolia was significantly exhibited much stronger activity than T. kotschyanus and usually one DOL was more susceptible to the essential oils.

Population density of *Edwardsiana rosae* L. and *Ardis brunniventris* Hartig on different genotypes of *Rosa damacena* in West-Azarbaijan province, Iran

Zohreh Nikoo[1], Hossenali Lotfalizadeh[2], Ismail Alizadeh[3], Mohammadreza Zargaran[4]

[1]Faculty of Agriculture, Tabriz Branch, Islamic Azad University, Tab, Iran, [2]East-Azerbaijan Research Center for Agriculture and Natural Resourc, Iran, [3]West-Azerbaijan Research Center for Agriculture and Natural Resour, Iran, [4]Agricultural Research Center, Iran

Rosa damascena Mill is one of the most important medicinal plants that use its ooze, distillates and oil. Various pests cause damage to ornamental and medicinal plant, annually. Because of unfavorable effects of pesticides in products of R. damascena and environmental ecosystem, using a combination of other control methods should be considered. Evaluate the population and damage of the pests in the different genotypes of Damask rose would be a noticeable step in this regard. During the 2010-2011 years, contamination of 36 genotypes of R. damascena was evaluated to important pest in the Urmia, West-Azarbaijan province. Field studies were carried out in damask rose in Saatlo Research Station, Urmia. Field samplings were carried out using different methods for each pest. Analyze of variance revealed a significant difference between genotypes. The lowest density of winter eggs of Edwardsiana rosae L. were observed on 1, 12, 16, 22, 10 and 14 genotypes originated from East-Azerbaijan, Zanjan, Fars (No.1), Kohkluye, Gom and Semnan (No. 2), but the highest prefer to spawning egg were observed on 39, 32, 35, 6, 17, 25 and 21 genotypes originated from Esfahan (No.7), Yazd (No. 2), Esfahan (No. 2), Ilam, Fars (No. 2), Gilan and Kermanshah The lowest contamination to Ardis brunniventris Hartig has been observed on 29, 13, 14, 17, 18, 30 and 7 genotypes originated from Hormzgan, Semnan (No.1), Semnan (No. 2), Fars (No. 2), Gazvin, Hamadan and Tehran.

Biological controllers of *Opsiphanes cassina* (Lepidopterous: Brassolidae) in plantations of African oil palm, Venezuela, South America

Paulo Beserra Maia

Instituto Nacional de Investigaciones Agricolas INIA, Venezuela, Bolivarian Republic of

The African oil palm is attacked by insects pest as Opsiphanes cassina, fact that reduces the productivity of the plantations. The aim of the study was to determine the relation between these insects pest, their parasites and the plants weeds present in oil palm plantation, Zulia state, west of Venezuela. The immature specimens of O. cassina were captured in field and supported in cages, where the parasites emerged of the pustules was captured. Also they were captured parasites in the weeds Senna reticulata, Solanum hirtum and Solanum sp. was calculated the index of diversity of Shannon-Weaver (H') and the parasites were identified. Thirty species of insects parasites were captured; 5 parasitized the individuals of O. cassina: Conura sp1, Conura sp2 and Conura sp3, Brachymeria sp and Cotesia sp. The biological diversity of the community of insects parasites was of: 1,22, 0,25 and 0,24 in Senna reticulata, Solanum hirtum and Solanum sp, respectively. The 5 species of parasites were always present in Senna reticulata, with exception Conura sp3, that also appeared in Solanum hirtum and in Solanum sp. Was not find statistically significant differences ($p<0,05$) between the populations of 5 species of parasites and the studied weeds. One found a relation of parasitism between 5 species of wasps and O. cassina. These species of parasites are associated with the present weeds in the plantations of oil palm, which might be used in the managing of this insects pest.

Predatory Efficiency of *Chrysoperla zastrowi* sillemi (Esben-Peterson) and *Cryptolaemus montrouzieri* Mulsant on *Paracoccus marginatus* and *Phenacoccus solenopsis* infesting Sunflower

Mariappan Suganthy[1], Periyaswamy Sakthivel[2]

[1]*Tamil Nadu Agricultural University, India,* [2]*Tamil Nadu Agricultural University, Coimbatore, Tamil Nadu, India*

Predatory potential of Chrysoperla zastrowi sillemi and Cryptolaemus montrouzieri on Paracoccus marginatus and Phenacoccus solenopsis infesting sunflower was studied. Results revealed that grubs of C. zastrowi sillemi fed 6.2 ± 1.1, 448.0 ± 76.4 and 68.8 ± 9.5 ovisacs, nymphs and adults of P. marginatus and 426.2 ± 9.2, 150.7 ± 3.3, 294 ± 4.0 first instar, second instar and third instars of P. solenopsis to complete their life stages. Similarly, grubs of C. montrouzieri fed 7.6 ± 0.7, 153.6 ± 23.8 and 62.8 ± 11.6 ovisacs, nymphs and adults of P. marginatus and 92.2 ± 8.5, 57.4 ± 5.8 and 22.2 ± 4.7 first, second and third instars of P. solenopsis, respectively to complete their life stages. Third and fourth instar were voracious and consumed 2.2 ± 0.4, 43.6 ± 2.0 and 23.2 ± 3.0 and 2.8 ± 0.4, 69.6 ± 4.6 and 27.6 ± 4.6 ovisacs, nymphs and adults of P. marginatus and 20.4 ± 2.0, 16.8 ± 1.6 and 9.2 ± 1.7 and 51.8 ± 3.2, 32.8 ± 2.7 and 11.6 ± 2.1 first, second and third instars of P. solenopsis, respectively. Adult C. montrouzieri consumed on an average 5.2 ± 0.8, 101.2 ± 13.5 and 35.4 ± 8.6 ovisacs, nymphs and adults of P. marginatus and 118.6 ± 10.4, 198.6 ± 15.0 and 42.2 ± 4.7 first, second and third instars of P. solenopsis, respectively. It is concluded that C. zastrowi sillemi and C. montrouzieri can be effectively employed in the management of sunflower mealybugs.

Classical biological control of papaya mealybug, *Paracoccus marginatus* (Williams and Granara de Willink) using Acerophagus papayae (Noyes and Schauff) in Tamil Nadu, India

Periyaswamy Sakthivel[1], P Karuppuchamy[2], Mariappan Suganthy[3], Thulasy Srinivasan[4]

[1]Tamil Nadu Agricultural University, Coimbatore, Tamil Nadu, India, [2]Tamil Nadu Agricultural University, Coimbatore, Tamil Nadu, India, [3]Tamil Nadu Agricultural University, Coimbatore, Tamil Nadu, India, [4]Tamil Nadu Agricultural University, Coimbatore, Tamil Nadu, India

Paracoccus marginatus is a polyphagous pest recorded from 135 host plants. It was recorded in papaya for the first time in Coimbatore, Tamil Nadu, India during July, 2008. Classical biological control was identified as an important component in the management of P. marginatus. Field efficacy of A. papayae on P. marginatus showed significant variations among pre and post-release counts. Population of P. marginatus ranged from 17 to 59 per 2.5 cm2 leaf area before release of parasitoid. Thirty days after release (DAR), the population of mealybug ranged from 8 to 23 per 2.5 cm2 leaf area corresponding to a reduction of 38.9 to 70.6 per cent. In unreleased field, the mealybug population was 28 at one month after release. At 60 DAR, significant reduction in the mealybug population was observed in all locations. Mealybug population ranged from 0 to 6 per 2.5 cm2 leaf area and reduction in population ranged from 72.2 to 100 per cent. Data on recovery of A. papayae revealed that maximum recovery of 81.3 per cent was recorded at 30 DAR. This confirms the establishment of A. papayae at all the experimental fields where the parasitoids were released. In unreleased field, 9.6 per cent recovery was obtained at 30 DAR. At 45 DAR, 68.7 to 89.6 per cent recovery was observed at different locations. In unreleased field, 16.7 per cent recovery was obtained at 45 DAR. The results revealed the establishment and recovery of A. papayae in all the fields providing successful control of P. marginatus.

Preliminary study of *Oligonychus afrasiaticus* predators in Manoojan (south of Iran)

Sadegh Farzan[1], Mina Khalilzadeh[2], Mahdieh Asadizeidabadi[3]

[1]Shahid Bahonar University of Kerman, Iran, [2]Shahid Bahonar University of Kerman, Iran, [3]Shahid Bahonar University of Kerman, Iran

During recent years, Oligonychus afrasiaticus (McGregor, 1939) has been one of the major pests of date palms in Iran (Kamali et al., 2001). To investigate the natural enemies of this pest, a faunistic survey of predatory mites was done during 2010-2011 in Manoojan. Pest colonies on the green fruits was collected and sampled. A total of six species was collected from which, Molothrognathus mehrnejadi and Neoseiulus barkeri were the most abundant species respectively. Collected predatory mite species are as follows: Raphignathidae Raphignathus hecmatanaensis Kanjani & Ueckermann, 2003 Bdellidae Spinobdella Cornini Baker & Balock, 1962 Phytoseidae Neoseiulus barkeri Huges, 1948 Stigmaeidae Cheyletostigmaeus sp. Caligonellidae Molothrognathus mehrnejadi Liang & Zhang 1997 Cunaxidae Lupaeus Lectus Catro & Den Heder,2009 Kamali, K., Ostovan, H. & Atamehr, A. (2001) A catalog of Mites & Ticks (Acari) of Iran. Islamic Azad University Scientific Publication Center. Tehran, 127 pp. McGregor, E.A. (1939). The specific identity of the American date mite; description of two new species of Paratetranychus. Proceedings of the Entomological Society of Washington, 41: 247-256.

The report of some typical oriental water mites (Acari: Hydrachnidia) from another province in south of Iran (Manoojan)

Saeid arjmand[1], isa etemadi[2], Mahdieh Asadi[3]

[1]Professor. Hesabi institute of Manoojan, Manoojan, Iran, Iran, [2]vali-e-asr university of Rafsanjan, Iran, [3]Shahid Bahonar University of Kerman, Iran, Iran

A big part of Iran is placed in Palearctic region, but south of Iran is transitional between the Palaearctic, Oriental and Afrotropical region, and a hot belt in the south of Iran (Sistan va Baluchestan, Hormozgan) is often regarded as a part of the Oriental region. In a faunistic survey of water mites done in the south of Kerman province in 2011, eight families of water mites collected. One new genus and three species were described as new for science (Asadi et al., 2010) The most interesting point is that It seems that fauna of streams and pools near Manoojan is different from other part of Iran and contain typical Oriental elements. With regards to the previous work in kerman province and the faunal structure of this part of Iran (Asadi, 2010), it seems that this boundary is placed in Kerman province. More investigation will help us to detect this boundary in south of Iran. All of the species collected are as follows; oriental typical species are marked by asterisk. Hydrodroma reophila Cook, 1967 Sperchon (Hispidosperchon) papillosus Thor, 1901 Axonopsis (Hexaxonopsis) manoojani Pesic & Asadi, 2010 Axonopsis (Hexaxonopsis) iranica Pesic & Asadi, 2010 Limnesia kochi* Smit & Pesic, 2010 Limnesia (Tetralimnesia) pinguipalpis* Cook,1967 Neumania maharashtris* Cook,1967 Neumania indentata* Smit & Pesic, 2010 Hygrobates fluviatilis Stom,1768 Iranobates hesabii Pesic, Smit & Asadi, 2011 Atractides omanensis* Smit & Pesic, 2010 Nilotonia persica Pesic & Saboori, 2006 Oxus cf. angustipositus K. First report of the marine water mites *Pontarachna arabica* (Hydrachnidia : Pontarachnidae from Iran

Isa Etemadi[1], Mahdieh Asadi[2], Malihe Latifi[3]

[1]Vali-e-asr University of Rafsanjan, Iran, [2]Shahid bahonar University of Kerman, Iran, [3]Vali-e-asr University of Rafsanjan, Iran

Pontarachnidae are one of the least know water mite families, Nothing is not know about their life cycle, hosts or food. They occur almost worldwide, but most species are found in subtropical or tropical areas. A few species have been found in freshwater, but all of these occur in estuaries or locations near the seas (Smit, 2008). During a sampling in the sea shores of Persian Gulf and Oman Sea in May 2012 this family collected and identified as Pontarachna arabica Pesic, Chatterjee & Ahmed Abada, 2008. This family and species reported for the first time from Iran and the male of this insect is under describing for the first time.

Acetylcholinesterase insertional mutations in insecticide-resistant populations of Colorado Potato Beetle, *Leptinotarsa decemlineata* (Say)

Maryam Malekmohammadi[1], Mir Jalil Hejazi[2], Mohammad Saeed Mossadegh[3], Hamid Galehdari[4], Mohammad Khanjani[5], Mohammad Taghi Goodarzi[6]

[1]Bu Ali Sina University, Iran, [2]University of Tabriz, Iran, [3]Shahid Chamran University, Iran, [4]Shahid Chamran University, Iran, [5]Bu Ali Sina University, Iran, [6]Hamedan University of Medical Sciences, Iran

Insecticide-resistant populations of Colorado potato beetle (CPB), with insensitive acetylcholinesterase (AChE) have recently been reported from commercial potato fields of Hamedan province in west of Iran. PCR-SSCP method was used to find sequence variation in the AChE gene. Based on the published nucleotide sequence information on AChE gene (GenBank L41180.1), five primer pairs were designed to amplify specific PCR products of 306 bp (first fragment: codons 24 through 142), 370 bp (second fragment: codons 141 through 261), 403 bp (third fragment: codons 248 through 381), 335 bp (fourth fragment: codons 376 through 486), and 335 bp (fifth fragment: codons 488 through 598), respectively. No specific PCR product of desirable size for either the fourth and fifth fragments could be obtained. The DNA amplification products were subjected to SSCP analysis to identify the DNA sequence variations between the susceptible strain and resistant populations. Alignment of the AChE gene sequences with the sequencing results revealed 25 single-base insertional mutations at nt 303, 305, 340, 605, 607, 764, 772, 855, 856, 891, 892, 897, 1084, 1099, 1113, 1137, 1147, 1178, 1195, 1246, 1247, 1248, and 1249 from the field populations of CPB, which may contribute to the AChE insensitivity. Further analysis on the RNA level is necessary for clarification and validation of this contention.

PGPR as biofertilizers: Their impacts on productivity of lentil and ckickpea and population incidence of associated insect fauna

Muhammad Dildar Gogi[1], Muhammad Ashfaq[2], Muhammad Jalal Arif[3], Muhammad Irfan Ashraf[4], Rashad Rasool Khan[5], Muhammad Rafiq Shahid[6]

[1]University of Agriculture, Faisalabad, Pakistan, [2]University of Agriculture, Faisalabad, Pakistan, [3]University of Agriculture, Faisalabad, Pakistan, [4]University of Agriculture, Faisalabad, Pakistan, [5]University of Agriculture, Faisalabad, Pakistan, [6]University of Agriculture, Faisalabad, Pakistan

Beneficial rhizosphere microorganisms are generally classified into plant growth promoting microorganisms (PGPM) that directly promot the plant growth and biological control agents (BCA) that indirectly contribute to plant productivity through the control of plant pests. Some species of microorganisms including mycorrhiza, pseudomonas and nitrogen-fixing bacteria are considered as mediators of paramount importance for the determination of nature and type of interactions between plants and herbivores (Barbosa et al. 1991). These studies were carried out to investigate the impact of a two formulations/mixtures biofertilizers i.e., FOR-1 (consisting of three strains of plant growth promoting rhizobacteria (PGPR) i.e., J1, JH4 and B5) FOR-2 (consisting of four strains of plant growth promoting rhizobacteria (PGPR) i.e., LLR3, LC3, CB5 and LC4) on the productivity of two pulses (lentil and chickpea) and incidence of insect fauna (both beneficial and pest insects). The application of both formulations of PGPR induced significant effects on the productivity of both pulses intern of yield ($p<0.01$) and resulted in 2-3 times more yield than conventional application of synthetic fertilizers. Similarly, PGPR application also promoted the host plant resistance enhancing the nutrient availability and leaf contents of treated plants as compared to synthetic fertilizers. In PGPR treated plots, higher numbers of beneficial insect fauna and lower number of insect pest fauna was observed as compared to plots which were treated with synthetic fertilizers. The results emphasized the promotion of PGPR application in pulses agroecosystem. The regression and correlation results is also discussed.

Investigations on development stages of *Lucilia caesar* Linne, 1758 (Calliphoridae: Diptera) in terms of forensic Entomology

Hulya Aksoy Aydınlı[1], Hakan Calıskan[2]

[1]*Eskisehir Osmangazi University, Turkey,* [2]*Eskisehir Osmangazi University, Turkey*

Calliphoridae family larvae are important for forensic entomology. For that reason development biology of larvae are very important. Larvae and adult stage nutrition habits are different at members of that family which get holometabol metamorphosis. In generally Calliphoridae species lives on that dead or living in at larval stages. Species that lives on dead in at larval stage helps for ecological balance by easier to take to pieces and decay. On the other hand classes which lives on living in at larval stage causes "Myiasis" illness. Larvae that have the ability of take texture in to pieces very faster, uses in uncured bruise. This study make with samples taken by one stations in city Eskisehir in TURKEY. For continue that study putrid hepatic pieces had put at station and egg packets add together over that hepatic. Egg packet which are in Calliphoridae family and the time of larval stages to reach adult. At that study one base family inculudes one genus and one species Lucilia caesar Linne, 1758, had fasten down. It has seen that development of investigated with Lucilia Caesar at 15-19 days were finished.

Sustainable agriculture through a miracle plant of Pakistan

Muhammad Ashfaq[1], Shahzad M. Basra[2], Umair Ashfaq[3]

[1]University of Agriculture Faisalabad, Pakistan, [2]University of Agriculture Faisalabad, Pakistan, [3]Government College University Faisalabad, Pakistan

Forests play a major role for economical and environmental benefits of man. Plants are valuable for us in many ways, besides protecting and improving the environment in' which we live, they control run off, check floods and soil erosion, improve soil fertility and help in reducing temperature and pollution. Regarding all the benefits associated with plants, Moringa tree is most suited to the people of Pakistan. It is considered one of the world's most useful trees, as almost every part of the Moringa tree can be used for food or has some other beneficial property. It is widely used as food and medicine for both human and other animals. Oil of Moringa retains the properties of use as biofuel, pesticide and natural oil. For evaluating the efficacy of Moringa plant, a study was conducted at Faisalabad and Moringa Leaf Extract was used as foliar application in wheat under field conditions. An increase of 10.73, 6.00, 10.70 and 4.00% was seen in 1000 grain weight, biological yield, grain yield and harvest index respectively, when crop was sprayed with MLE at tillering + jointing + booting + heading. MLE can also be used as priming agent in hybrid maize.

Using species of Ephemeroptera as saprobic indicator to determine water quality in Sultansuyu stream (Malatya, Turkey)

Caner Aydinli
Anadolu University, Turkey

1795 Ephemeroptera (Insecta) nymph samples from 7 localities in Sultansuyu Stream (Malatya) were collected and investigated. From these nymph samples, 14 species belonging to 10 genera in 6 families were determined. The species determined in the research area was also evaluated according to saprobic system and tried to determine water quality of Sultansuyu stream. When water quality evaluated according to dominance analysis at genus level, results did not show compliance with water quality observed in studying area. For this reason, water quality, were conducted with the species level. According to the results of this study, it is determined that 7th and 6th localities which were near to spring showed the characteristics of clear water (oligosaprobic), 5th and 4th localities showed the characteristics of little dirty (β-mesosaprobic) and the localities from 3rd to 1st showed the characteristics of dirty water (α-mesosaprobik).

Determination of diazin pesticide residue in rice by gas chromatography /mass spectrometer in Mazandaran Province in Iran

sohrab imani[1], Shahrzad Mohammadi[2], Ahmad reza Golmohammadi[3], Sina Imani[4]

[1]Islamic Azad University, Science and Research Branch ,Tehran., Iran, [2]Islamic Azad University, Science and Research Branch ,Tehran, Iran, [3]Islamic Azad University, Science and Research Branch ,Tehran, Iran, [4]UCSA, Kuala Lumpur,Malaysia, Iran

The application of pesticides is essential in effectively controlling pests and any inappropriate use of pesticides could cause residue problems. Rice is one of the most important food sources of people in the world. Chilo suppresalis is its key pest in Mazandaran province and Diazinon is the most common pesticide that is used against it. Due to the importance of this product & regarding the fact that it provides two-third of people's daily calories in the Asian region this study is conducted for the awareness of Marketed rice of contamination of Diazinon residue in this area which has the first rank in the amount of cultivation of desired product .Thirty two samples were randomly collected from the Mazandaran province farms and stores. In the laboratory, each sample was extracted with using Solid Phase Extraction method and the final extracts were injected into Gas Chromatography /Mass Spectrometer (GC/MS) system. Obtained data were compared with WHO/FAO Codex Alimentary Commission by T-test. Results showed pesticide contamination in all cases and their volumes were from 0.007 to 2.26 ppm .In 13 cases of stored samples & 6 cases of farm ones the contamination exceeded Maximum Residue Limit ,i.e. 81/42% , 38.88% . Recovery test at two levels (0.1 and 1 ppm) with 3 replicate was done and the result average was 94.8% .So this method provides reliable and accurate results and it shows that they will be a serious threat to health if they are not properly controlled.

Epidemiological aspects of human myiasis in Iran

Javad Rafinejad[1], Kamran Akbarzadeh[2], Akbar Biglarian[3], Fariba Biclarian[4], Atiyeh Rafinejad[5]

[1]Tehran University of Medical Sciences, Iran, [2]Tehran University of Medical Sciences, Iran, [3]University of Social Welfare and Rehabilitation Sciences, Iran, [4]Tehran University of Medical Sciences, Iran, [5]Tehran University of Medical Sciences, Iran

Myiasis is a common disease in Iran. In this study we evaluate knowledge, community perceptions and practice about myiasis and also find medical importance of human myiasis in Fars province. A descriptive cross sectional survey using semi-structured questionnaire was used in the study area. A total of 302 cattle keepers, shepherd and butchers questioned randomly in the area of study. Data were analyzed by SPSS 16 software. Near to 30% of the surveyed population were illiterate. Majority of them(88.3%) have been stricken at least once myiasis during their job experiences. The frequency of the disease in the patients was 1 to more than 30 times. Close to 71.5% of them had been infected out of the barns. Pharyngeal myiasis can be expected in at least 87% of patients. The causing agent for the patients was sheep botfly, Oesteru ovis (Diptera: Oesteridae). Continuously painful throat irritation, itching, watery eye and runny nose are the common symptoms of the disease. Duration of remission of the disease was more than 5 days. Despite of more variation in academic educational levels of the surveyed community, their health educational level seems to be more similar. Age and job experiences had effect neither on their knowledge nor on their practice. Their academic educational level also had no significant effect on their knowledge but it had significant effect on their practice. It can be concluded that a comprehensive and continued educational program is needed to aware the people about myiasis, its prevention and control.

Chemical analysis of spinach resistance to aphids and leaf miners

Nasir Masood
The Islamia university of bahawalpur, Pakistan

Host plant resistance is an essential factor of integrated pest management (IPM) while understanding the biochemical mechanisms could speed up the resistance breeding. To study the biochemical mechanisms of spinach plant resistance to its major insect pests, leafminer (Liriomyza langei) and aphids, sixteen Spinach genotypes with various degree of resistance were planted in growth chambers and a field with four replications. Sugars, protein, chlorophylls, carotenoids, and phenolics were extracted from plant leaves, and damage by leafminers and numbers of aphids in different species were recorded. Leafminer stings per cm2 leaf area of young plants were highly correlated with sting/cm2 of mature plants. This suggests that leafminer-resistant varieties for mature spinach plants may also be deployed for baby leaf production. Sucrose concentration of young plants was correlated with leafminer stings per cm2 leaf ($r = 0.729$, $p = 0.01$) and mines per plant ($r = 0.789$, $p = 0.01$), suggesting that low sucrose content could be used as a marker for early screening or selection for leafminer resistance. Leafminer stings/cm2 were negatively associated with contents of flavonoids ($r = -0.558$, $p = 0.05$) and chlorogenic acid ($r = -0.5978$, $p = 0.05$), while mines per plant were negatively associated with concentrations of flavonoid ($r = -0.701$, $p = 0.01$), chlorogenic acid ($r = -0.592$, $p = 0.05$) and rutin ($r = -0.601$, $p = 0.05$), implying a role of phenolics in the leafminer resistance.

Biology of *Phalantha phalantha* duraury (Lepidoptera : Nymphalidae) an injurious pest of well known medicinal plant *Withania somnifera* Dunal

Mahadeo Gorain

National Centre for Cell Science, India

Studies on the biology of Phalantha phalantha Drary (Lepidoptera: Nymphalidae) has been recorded on the host plant of Withania somnifera Dunal (Ashvangandha). The gross morphology and duration of various developmental stages has been recorded. The larval and oviposition behaviour has been studied in detail. Nectar food plants of the adult and ontogenetic variability in larval stage has been recorded. The adult butterfly is orange colored with black markings on the wings. Length of female butterfly is 18.67 ? 0.24 mm with a wing span of 56.33 ? 0.16mm. The length of male butterfly is 13.8 ?0.34 long and the wing expanse is 45.20 ? 0.43 mm.

Survey of relationship between birds damage and morfological characteristics of sunflower

Esmaeil Alizadeh
Agricultural Research Center, Iran

Survey of the caused damage by the birds on the sunflower fields in different planting dates in west Azarbaijan Esmaeil Alizadeh¹(Email:ISM478@Yahoo.com) and nouraddın shayesteh 1 - Agricultural and Natural Resources Research Center of West Azarbaijan. Urmia--P.O.Box : 365. 2-islamic azad university,mahabad branch-mahabad-iran Birds are among the most important pests in the fields under sunflower cultivation that lead to huge annual losses of the crop. Out of the deleterious birds of sunflower fields, house sparrow (Passer domesticus) causes the most abundant damage in the regional fields of sunflower. The present investigation was carried out to evaluate house sparrow damage on sunflower cultures in the Agricultural and Natural Resource Research Station of Khoy since 2006 in a biannual research project. The main plots included four seeding dates with 15 day intervals and the accessory plots were three sunflower cultivars Alstar, Euroflor, and KSC43/128. The cultivars were seeded in the Khoy station and the rates of bird damages were calculated at the end of seed maturity period. Based on variance analyses of data, seeding dates and cultivars had highly significant impacts on sunflower yield and the damage rate. The highest protected yields were resulted from the first and the second seeding dates exceeding 2500 kg/ha. However, the most damage rates were also calculated with the first and the second seeding dates, respectively rated as 96% and 93%. The damage rate in the second year was higher than that in the first year. Among the tested cultivars, the hybrid Alstar was of the highest

Quantitative and qualitative wheat loss assessment at different storage structures

Shahzad Saleem[1], Mansoor ul Hasan[2], Muhammad Sagheer[3], Sohail Akhtar[4]

[1]University of agriculture Faisalabad, Pakistan, [2]University of Agriculture Faisalabad, Pakistan, [3]University of Agriculture Faisalabad, Pakistan, [4]University of Agriculture Faisalabad, Pakistan

A laboratory experiment was conducted to evaluate the qualitative and quantitative wheat loss assessment in different storage structures. Cereal grains are the major source of food for humans and most domesticated animals. Wheat storage losses were assessed by sampling wheat from five storage structures (Tandlianwala, Mamookanjan, Buchiana, Jaranwala and Sumundri). Quantitative losses were assessed by counting and separating insect pest infected damaged, black headed, shriveled, broken grains and foreign matter in wheat at average or percentage basis which showed that stored wheat has more damaged and insect infested grains then fresh wheat sample. Wheat samples were chemically analyzed to calculate the loss in quality by comparing their Ash percentage, Moisture percentage, Percent protein contents and Percent fat contents with the fresh wheat samples. Moisture contents were having the mean 8.489 % in fresh wheat stock and 10.452 % in stored wheat. The protein contents were having the mean 13.763 % in fresh wheat stock and 11.333 % in stored wheat. The crude fat contents were having the mean 5.812 % in fresh wheat stock and 4.925 % in stored wheat. The ash contents were having the mean 1.327 % in fresh wheat stock and 1.215 % in stored wheat.

The genetic diversity of water mite Hygrobates fluviatilis (Acari: Hydrachnidia) evaluated based on eight microsatellite loci (HfMS01, HfMS02, HfMS08, HfMS09, HfMS014, HfMS029, HfMS033 and HfMS040; Asadi et al., 2009). Eight populations collected from two different types of habitats (springs and streams) were evaluated. Data were analyzed based on UPGMA method using Popgene software. The number of alleles detected ranging from 2 to 21 (average, 9.23 per locus). The observed heterozygosity ranged from 0.063 to 0.813. Of 13 primers, four populations from spring and four from stream were tested and 292 alleles were totally detected. The total amount of gene diversity ranged from 0.722 (locus Hf09) to 0.945 (locus Hf29) and 0.872 (average per locus). Eight populations were detected in two separate groups. The genetic distance between habitats was high, which means that the genetic differences were caused by habitat differences. The results also indicated that polymorphic microsatellites provided a clear differentiation between spring and stream populations which was not found in our previous study based on mitochondrial cytochrome c oxidase subunit I (COI) gene (Asadi et al., 2012). Asadi M, Higaki T, Hinomoto N, Saboori A, Naghavi MR (2009) Isolation and characterization of polymorphic microsatellite loci from the water mite Hygrobates fluviatilis (Acari: Hydrachnidia: Hygrobatidae). Molecular Ecology Resources 9:793-795. Asadi M, Hinomoto N, Saboori A, Javan-Nikkhah M (2012) Genetic diversity in mitochondrial cytochrome c oxidase subunit I sequences of the water mite Hygrobates fluviatilis (Acari: Hydrachnidia: Hygrobatidae). International Journal of Acarology38:96-100.

A preliminary documentation of consumable Acridid (Orthoptera) species worldwide

Amlan Das[1], Klaus Riede[2]

[1]Dinabandhu Mahavidyalaya, (West Bengal State University), India, [2]Global Register of Migratory Species- www.groms.de, ZF Museum Alexander Koenig, 53113 Bonn, Germany

Insects are seldom been seriously considered as possible nutrient source for animal husbandry or for human consumption, although scattered literature supports that being of its high protein content some insects are used as feed or feed ingredient or for human consumption since long. Among insects, grasshoppers and locusts (Orthoptera) have some advantageous properties in favour of entomophagism or feed component. The present investigation performed data-mining, using DORSA (http://www.dorsa.de) and OSF (http://orthoptera.speciesfile.org) and isolated 55 Acridid species (Orthoptera) consumed by people from 29 countries worldwide. We identified the species mainly from two museum sources from Bonn and Berlin, Germany. Mean length, pronotum-width, head-width of both sexes of 55 species with their corresponding volumes were measured. Among 55 species the longest species lengths (mm±SD) were 47.29±1.24 (among males) and 67.7±3.28 (among females) where the shortest species lengths were 14.17±1.11 (among males) and 16.17±0.7 (among females). The minimum and maximum head-widths (mm±SD) were recorded as 1.77±0.18 and 6.2±0.07 (males) and 2.57±0.35 and 7.82±0.37 (females). Out of 55 species, nutritional values of some fresh available species/genus were estimated in laboratory and that estimations for the rest unavailable species/genus were tabulated using available published records. Generally Orthoptera do have 22.8% (minimum) to 65.39% (maximum) crude protein with an average of 44.1% (dry matter) and those findings very much corresponds with our results (60.2% to 68.1%). Once the full compilation of data, principally culture procedure, breeding potential and nutritional values of recognized species are available, viable species of Acridids to be cultured economically can be selected.

Species richness & abundance of Arctiinae (Erebidae: Noctuoidea) in Western Ghats of India

Navneet Singh[1], Jagbir Singh[2]

[1]Zoological Survey of India, Kolkata, India, [2]Punjabi University, Patiala, Punjab, India

The Western Ghats of India are acclaimed as one of the biodiversity hot spots of the Globe. Originating from the mouth of river Tapti (Gujarat) & running along the West coast of India, they cover an area of 160,000 sq. km & stretches for 1600 km to Kanyakumari in Tamil Nadu. Being one of the richest areas of biological wealth, Western Ghats exhibit a vast range of biotic provinces coupled with high degree of endemism. Insects, which constitute 66% of the total animal kingdom, play a vital in the development & maintenance of such biotic provinces with which the future of humans is inextricably linked. Present study deals with the species richness and abundance of such an economically important group of insects i.e. arctiinae (Erebidae: Noctuoidea: Lepidoptera) from Western Ghats of India. More than 40 localities of Western Ghats were selected as sample sites, to which, repeated collection visits yielded a total number of 1650 representatives of 101 species under 46 genera of arctiinae. Two genera and eight species were reported for the first time from India whereas, the extended distributional limits of other eleven species were also reported. It was observed that some of the localities were proved to be excellent for arctiin diversity and others were restricted to few species or specimens. This research work is first of its kind on arctiin moths from Western Ghats of India and definitely, an addition to the existing knowledge about this group. The details are discussed.

Antimicrobial activity and composition of *Artemisia judaica* L. essential oil from Egypt

Omar Mohamed Zayed[1], Hany Kamal Abd El-Hady[2]

[1]*Menofia University, Egypt,* [2]*Menofia University, Egypt*

Artemisia judaica is a widely distributed plant in the Middle East (Sinai Peninsula, Jordan and Saudi Arabia). The antimicrobial activity of essential oil derived via hydro-distillation method from aerial parts of A. judaica L., were evaluated for antimicrobial activities. Two Gram-positive bacteria (Bacillus subtilis and Streptomyces spp.); one Gram-negative bacterium Escherichia coli O157; five fungi strains (Fusarium oxysporum, Rhizopus stolonifer, Rhizoctonia solani, Macrophomina phaseolina and Aspergillus niger) and three yeasts (Candida albicans, Candida tropicalis and Saccharomyces cerevisiae) were used for evaluation of antimicrobial activities of A. judaica essential oil. The agar gel diffusion method was used to assay for the antimicrobial properties on the test isolate. The activity was more pronounced against Gram-positive and candidal than against fungal organisms except R. stolonifer. The chemical composition of the essential oil was analyzed by GC-MS and the resulting oil contained piperitone (32.4%), camphor (20.6%) and E-ethyl cinnnamate (8.2%) as major components, which may provide the antimicrobial properties of the essential oil against tested organisms.

Keywords:*Artemisia judaica, Essential oil, Antimicrobial activity, GC, MS analysis, Chemical composition*

Pollen analysis in honeys collected from Karnataka region of Nilgiri Biosphere, South India

Sivaram Venkataramegowda[1], Roopa P[2], Shubharani Ramanath[3], Guntima Suwannapong[4]

[1]Bangalore University, Bangalore, India, [2]Bangalore University, Bangalore, India, [3]Bangalore University, Bangalore, India, [4]Burapha University Chon Buri province, Thailand

The present work refers to the pollen analysis of 15 honey samples collected from three locations from Karnataka region of Nilgiri Biosphere, South India. The honey samples were collected from the domestic bee hives of Apis cerena and wild bee hives of Apis dorsata from local honey hunters of forest most represented families. Ther was a dominance of tree species which are the most preferred and highest contribution for nectar and pollen source for honeybees in the study area. This study discusses regions during March 2010 to October 2011. Pollen analysis was performed using acetolysis method . the samples were subjected to both qualitative and quantitative analysis. Out of 15 samples analyzed one sample was recorded as unifloral, which contains Coffea sp., as predominant pollen and remaining 14 honey samples were recorded as multifloral. Fabaceae, Asteraceae and Myrtaceae were the honey plant resources and potentialities for commercial beekeeping in Nilgiri Biosphere.

Phisicochemical characteristics and pollen analysis of honeys from western ghats of Karnataka, South India

Shubharani Ramanath[1], Sivaram Venkataramegowda[2]

[1]Bangalore University, Bangalore, India, [2]Bangalore University, Bangalore, India

The present study intended to determine a quantitative and qualitative analysis of 30 honey samples collected from honeybee colonies in different locations of Western Ghats of Karnataka, Out of which, 9 samples were found to be unifloral and 21 were multifloral. In unifloral honey samples, Sapindus laurifolia, Hevea sp., Areca catechu, Acacia sp., Mangifera indica, Terminalia bellerica, Syzygium sp., Pongamia pinnata, and Eucalyptus sp., were predominant pollen types. These samples were also analysed for several physicochemical parameters and recorded. The honey samples had moisture ranged from 7.4% to 32.5%, ash varied from 0.16% to 0.85%, pH in the range of 3.2 to 4.5, free acidity from 7.0meq kg to 39meq kg, reducing sugar from 60.2% to76.5%, total sugar from 64.2% to 81.6%, proteins from 0.22mg/100ml to 0.95mg/100ml, alkaloids from 2.0% to 19% and phenols from 20mg/100g to 96mg/100g. This type of physicochemical and pollen analysis of honey samples favors the possibility of utilizing the rich flora of Western Ghats for good quality honey.

Determination of major constituents of honeybee venom from Korea

SangMi Han[1], Haju Baek[2], HyungJoo Yoon[3], Joungmin Kim[4], Seohui Park[5]

[1]National Academy of Agricultural Science, RDA, Republic of Korea, [2]GyeongSangBukdo Government Public Institute of Health & Environment, Republic of Korea, [3]National Academy of Agricultural Science, RDA, Republic of Korea, [4]National Academy of Agricultural Science, RDA, Republic of Korea, [5]National Academy of Agricultural Science, RDA, Republic of Korea

The aim of the study was to the determination quantitatively of the major constituents of honeybee (Apis mellifera L.) venom from Korea by liquid chromatography. Samples of honeybee venom were purchased from Chungjin, Ibee and Sigma over two consecutive beekeeping season(2007-2008). The sephadex TM75 and source 15RPC ST column was applied. Several honeybee venom constituents were separated and the content of three of them (melittin, apamine and phospholipase A2) were determined. The chemical composition of honeybee venom from Korea were evaluated. Melittin content varied from 48.5 to 67.2 and averaged 50.7%. Apamin content camewithin a range of 2.0 to 3.2, and averaged 2.8%, and phospholipase A2 content was between 10.8 to 14.5, averaging 12.8%. There is no statistically significant differences for the content of the main component compared standard honeybee venom to domestic honeybee venom. The quantitative composition of melittin, apamine and phospholipase A2 may provide a basis for the development of the domestic standard for honeybee venom.

Keywords:*bee venom, Liquid chromatography, melittin, apamin, phospholipase A2*

Royal jelly reduces melanin synthesis through down regulation of tyrosinase expression

SangMi Han[1], Yoonhee Cho[2]

[1]National Academy of Agricultural Science, RDA, Republic of Korea, [2]National Academy of Agricultural Science, RDA, Republic of Korea

For cosmetic reasons, the demand for effective and safe skin-whitening agents is high. Since the key enzyme of the melanin synthetic pathway is tyrosinase, many depigmentating agents in the treatment of hyperpigmentation act as tyrosinase inhibitors. In this study, we have investigated the hypo-pigmentary mechanism of royal jelly in mouse melanocyte cell line, B16F1. Treatment of B16F1 cells with royal jelly markedly inhibited malanin biosynthesis in a dose-dependent manner. Decreased melanin contents occurred through the decrease of tyrosinase activity. The mRNA levels of tyrosinase were also reduced by royal jelly. These results suggest that royal jelly reduces melanin synthesis by down regulation of tyrosinase mRNA transcription and serve as a new candidate in the design of new skin-whitening or therapeutic agents.

Silk fibroin for guided bone regeneration

HaeYong Kweon
National Academy of Agricultural Science, Republic of Korea

Silk fibroin (SF) is a natural protein polymer spun by silkworm Bombyx mori and used as a typical textile fiber and a surgical suture. Recently, cytocompatibility and tissue-compatibility of SF has been investigated and elucidated that there is no severe side effect to cell and tissue. The author examined the feasibility of SF as eardrum membrane and it is good for regeneration of eardrum with high efficiency. To expand the usability of SF, the author examined SF for guided bone regeneration. SF membrane with bioactive materials was pre-pared and examined the morphology, structural characteristics, and thermal properties. And then it was applied to white rabbit to evaluate bone formation. Histomorphology and removal torque were analyzed.

Preparation and characterization of regenerated *Antheraea pernyi* silk fibroin

KwangGill Lee[1], HaeYong Kweon[2]

[1]*National Academy of Agricultural Science, Republic of Korea,* [2]*National Academy of Agricultural Science, Republic of Korea*

Antheraea pernyi silk fiber was dissolved in calcium nitrate solution with various dissolving conditions. The solubility was significantly dependent on the concentration of calcium nitrate, dissolving temperature and time. The aqueous solution of Antheraea pernyi silk fibroin was composed of a mixture of polypeptides with several molecular weights of above 14 kDa. FTIR and XRD showed that regenerated Antheraea pernyi silk fibroin was composed of a α-helix as well as random coil conformation while silk fiber was a traditional β-sheet structure. The endo-exo transition in temperature ranges of 228~232℃ also supports these conformations of regenerated silk fibroin film. TGA and DTG curves showed that thermal decomposition of regenerated Antheraea pernyi silk fibroin proceeded by three steps. The mechanical damping peaks (tan δ) were appeared at about 227℃ with minor shoulder maximum at about 240℃, which were somewhat lower than those of tussah silk fiber.

Thick flexible silk fibroin biological membrane

You Young Jo[1], HaeYong Kweon[2]

[1]National Academy of Agricultural Science, Republic of Korea, [2]National Academy of Agricultural Science, Republic of Korea

Silk is a natural polymer with biocompatibility and low inflammatory reaction. Recently, Silk fibroin has been studied in the biomedical application. In this study, we made thick silk biological membranes containing different concentrations of salt and examined characteristics of the membranes. Until now there was a limit to produce a thick silk membrane which has a thickness of more than 100 micrometer. But we overcome the existing difficulties and were successful in producing a thick silk biological membrane. We had produced a silk membrane with thickness of more than 500 micrometer. Salt addition increased the transparency and maximum stretching length of silk membrane. The membranes did not show cytotoxicity. These silk membranes are expected to be use as medical application for variety of purposes.

Pollinating activity of 3 species of insects, *A. mellifera, O. cornifrons*, B. *terrestris*, in Japanese apricot field

In Gyun Park[1], Mi-Ae Kim[2], Hyung Joo Yoon[3], Kyeong Yong Lee[4]

[1]National Academy of Agricultural Science, RDA, Republic of Korea, [2]National Academy of Agricultural Science, RDA, Republic of Korea, [3]National Academy of Agricultural Science, RDA, Republic of Korea, [4]National Academy of Agricultural Science, RDA, Republic of Korea

To increase the fruit quality of the Japanese apricot, 3 species of insects, Apis mellifera, Bombus terrestris and Osmia cornifrons were used for pollination in Japanese apricot field in Jinju and Sancheong province. And also economical effect for crops of Japanese apricot fruit pollinated with same insect was analyzed. This study was also conducted using 3 kinds of methods for pollination effect, natural condition, net-house and control method. Because blooming period of Japanese apricot was different from the other fruit tree(Blooming time of Japanese apricot shows always in the middle of the March), foraging behavior of insects used in this examination showed different tendency each other. Especially O. cornifrons was not adapted to wind and lower temperature compared with A. mellifera and B. terrestris in this field condition. Rate of fruit set pollinated with A. mellifera and B. terrestris was showed 14.9% and 13% respectively. Total rate of fruit set of Japanese apricot showed lower tendency compared with other kinds of fruit tree with under 30%. Quality of fruit pollinated with A. mellifera and B. terrestris showed higher than O. cornifrons in natural field condition in fruit weight.

The influence of soil exposure methods on toxicities of insect growth regulators (IGRs) for *Paranura rosea* (Collembola)

Yun-Sik Lee[1], Jino Son[2], Youngeun Kim[3], Somi Yu[4], Hyoung-Ho Mo[5], Kijong Cho[6]

[1]Korea University, Republic of Korea, [2]Nebraska University, U.S.A., [3]Korea University, Republic of Korea, [4]Korea University, Republic of Korea, [5]Korea University, Republic of Korea, [6]Korea University, Republic of Korea

Only information about mortality and juvenile production is obtained in existing Collembolan reproduction test. In this study, toxic effects of the three insect growth regulators (teflubenzuron, fenoxycarb, tebufenozide) were evaluated in the OECD artificial soil for determining potential and reliability of new exposure method. Several tests (1-2) were conducted. 1) The reproduction test using Paranura rosea was conducted in two different exposure conditions. One was existing method (ISO standard method) and other which was exposed in the compacted soil is new soil exposure method (surface contact only method). Several endpoints were examined after 28-day exposure. 2) Also some endpoints were compared with the result of solid leachate phase test using Microtox® for investigating toxicity change by time. In ISO standard method, median lethal concentration (LC50) for adult and median effective concentration (EC50) for juvenile was estimated, and in surface contact only method, LC50 for adult, EC50=egg for egg production and EC50=juvenile for hatched juvenile was estimated. Teflubenzuron which is the most toxic chemical showed high toxicity at all the end points. and fenoxycarb showed high ovicidal effect. Especially, for fenoxycarb, toxic effect was reduced as time passed. Tebufenozide showed relatively low toxicity. However, the toxicity of all the IGRs in ISO standard method was more toxic than that of the surface contact only method. Thus, to compare the result in ISO standard method with that in surface contact only method is good enough to trace the specific toxic effects of the test chemicals and provide additory endpoints.

Complete comparative genomic analysis of *Bombyx mori* nucleopolyhedrovirus-K1, K4 and K5 strains isolated in Korea

Won Il Heo[1], Jae Bang Choi[2], Sung Min Bae[3], Tae Young Shin[4], Yeon Ho Je[5], Byung Rae Jin[6], Soo Dong Woo[7]

[1]Chungbuk National University, Republic of Korea, [2]Chungbuk National University, Republic of Korea, [3]Chungbuk National University, Republic of Korea, [4]Chungbuk National University, Republic of Korea, [5]Seoul National University, Republic of Korea, [6]Dong-A University, Republic of Korea, [7]Chungbuk National University, Republic of Korea

The genome of three genetically distinct isolates of Bombyx mori nucleopolyhedroviruses (BmNPVs), BmNPV-K1, K4 and K5 strains isolated in Korea was completely sequenced and comparative analyzed. BmNPV-K1 consisted of 126,747 bp and 131 open reading frames (ORFs) of 150 nucleotides or longer with minimal overlap have been identified. In contrast, BmNPV-K4 and K5 consisted of 128,618 bp and 134 open reading frames (ORFs), 127,554 bp and 133 open reading frames (ORFs), respectively. Although gene arrangement is virtually identical, the genome of BmNPV-K4 was 1,871 bp and 1,064 bp longer than that of BmNPV-K1 and K5, respectively. The most interesting difference between these viruses was the presence or absence of baculovirus repeated ORFs (bro) genes. To investigate the relationship between BmNPV-K1, K4 and K5, phylogenetic analysis with each member of the paired ORFs was performed. The sequence data suggest that BmNPV-K1, K4 and K5 are closely related but have diverged and evolved into three separate strains. This was study to identify highly related but separately evolving viruses in the same insect host and geographic location. We are currently comparing the differences of these BmNPV genomes to elucidate function of novel genes.

Production of porcine circovirus type 2 capsid protein by the fusion expression with baculovirus partial polyhedrin in insect cells

Jun Beom Lee[1], Sung Min Bae[2], Hee Jung Kim[3], Won Il Heo[4], Jae Bang Choi[5], Tae Young Shin[6], Yeon Ho Je[7], Byung Rae Jin[8], Soo Dong Woo[9]

[1]Chungbuk National University, Republic of Korea, [2]Chungbuk National University, Republic of Korea, [3]Chungbuk National University, Republic of Korea, [4]Chungbuk National University, Republic of Korea, [5]Chungbuk National University, Republic of Korea, [6]Chungbuk National University, Republic of Korea, [7]Seoul National University, Republic of Korea, [8]Dong-A University, Republic of Korea, [9]Chungbuk National University, Republic of Korea

Porcine circovirus type 2 (PCV2) is a non-enveloped circular single-stranded DNA virus associated with postweaning multisystemic wasting syndrome, which is considered to be an important infectious swine viral disease. PCV2 capsid protein encoded by ORF2 is a major structural protein and expected as the high immunogenicity protein. For the efficient production of capsid protein, the recombinant baculoviruses were generated to express ORF2 of various fusion forms with a partial polyhedrin of Autographa californica nucleopolyhedrovirus. Recombinant capsid protein was produced successfully with fusion form of partial polyhedrin and the yield was high like as shown visible clearly on SDS-PAGE. Production and status of recombinant fusion proteins in insect cells were confirmed by SDS-PAGE and Western blot analysis using His-tag antibody, anti-ORF2 monoclonal antibody and anti-PCV2 serum. Optimal multiplicity of infection (MOI) and infection time for the production of recombinant capsid protein were determined as 5 MOI and 4 days, respectively. The results suggest that the fusion expression with polyhedrin is able to increase the production of recombinant PCV2 capsid protein in insect cells.

Antimicrobial effects on *Propionibacterium acnes* of extracts from Korean propolis

Soon Ok Woo[1], Sangmi Han[2], In-Pyo Hong[3], Yong-Soo Choi[4], Kwang-Gill Lee[5], Myeong-Lyeol Lee[6]

[1]National Academy of Agricultural Science, RDA, Republic of Korea, [2]NAAS, Republic of Korea, [3]NAAS, Republic of Korea, [4]NAAS, Republic of Korea, [5]NAAS, Republic of Korea, [6]NAAS, Republic of Korea

Propolis, or 'bee glue', is a complex resinous mixture of plant-derived products gathered, modified and used by bees as a general purpose sealer, draught excluder and antibiotic in their hives. The presence of propolis within the hive may also provide an environment not suitable for the growth of bacteria and other microorganisms. Propolis composition is directly related to that of bud exudates collected by bees from various trees. The composition of the propolis depends upon the vegetation of the area from where it was collected on the bee species. Propolis is an excellent material, as known as antimicrobial activity, propolis samples were collected in south korea, propolis extracted with ethanol(EEP), EEP was fractionated by prepHPLC, and antimicrobial activity against acne bacteria (Propionibacterium acnes) investigated. Antimicrobial activity was detected in the 2-3-5-4 fraction.

Development of 「Ecology experience kit displaying photo-tactic insects」 to activate the insect industry

JinGu Lee[1], HeeDong Kim[2], HaeGil Lee[3], SangHyun Lee[4], AeGyeong Seo[5], ChangSung Kang[6], YoungBo Lee[7], YoungKyu Park[8]

[1]Gyonggi-do Agricultural Research & Extension Services, Republic of Korea, [2]Gyonggi-do Agricultural Research & Extension Services, Republic of Korea, [3]Gyonggi-do Agricultural Research & Extension Services, [4]SUNYOU Co., Republic of Korea, [5]Gyonggi-do Agricultural Research & Extension Services, Republic of Korea, [6]Gyonggi-do Agricultural Research & Extension Services, Republic of Korea, [7]National Academy of Agricultural Science, RDA, Republic of Korea, [8]Korea Beneficial Insects Lab.,

It was carried out to develop the ecology experience kit displaying the photo-tactic insects to activate the insect industry. The kit was developed to have the characteristics of being moved with wheels in plain place and carrying by truck, and being used semi-permanently. To display the insects and plants, this kit was equipped with the electric lighting, natural ventilation and drain system. The 8 species of insects and 7 species of plants were selected as adaptable insects and plants for the kit. In the 8 species of insects, Pieris melete and Eurema hecabe were very suitable in the kit because of their small size and vivid flying activity. In particular, Baculum elongatum has several peculiarities like parthenogenesis, unique external features and dropping oviposition, it seemed to have worth as a industrial pet insect. The kit was expected to remind adults of nostalgia, to offer students the nature sense, and to increase the income of industrial insect farmers.

Trapping Time Effect on a Korean Strain of the Entomopathogenic Nematode, *Steinernema carpocapsae*

DongWoon Lee[1], Ho Yul Choo[2]

[1]*Kyungpook National University, Republic of Korea,* [2]*Kyungpook National University, Republic of Korea*

A Korean isolate of the entomopathogenic nematode (EPN) Steinernema carpocapsae KCTC 0981BP strain (ScK) is effective for control of many Korean agricultural and forestry pests. In vitro culture is available for large scale of mass production of commercial EPN, but it is a costly and complicated process, whereas in vivo culture using great wax moth Galleria mellonella larvae is simpler for small scale production. However, trapping time during in vivo culture may influence harvesting and survival of EPN. We investigated effects of this factor on harvest, survival, and pathogenicity of ScK. Elapsed time to first and maximum emergence of progeny (TFE and TME, respectively) from G. mellonella larvae was highly influenced by trapping time on the White trap. Emergence time was shorter with trapping on the White trap. The TFE was shorter in the 7th to 9th day trapping. TME was shorter in late trapping. Trapping time did not influence duration of emergence. Mean number of progeny was not significantly affected by trapping time except on the 9th day trapping.

Keywords:*Steinernema carpocapsae, Steinernemidae, white trap, in vivo production*

The chitinase gene of baculovirus is expressed in late phase of virus replication in insects and possesses high exo- and endo-chitinase activity, which can hydrolyze inherent chitin in insect body, thus promoting terminal host liquefaction. Nucleopolyhedrovirus (NPVs) viral chitinases (vChitA) have been well analyzed, but information is limited as regards to vChitA from granuloviruses (GVs). Whole-genome sequencing of the Korean isolate of Pieris rapae GV proposed a putative chitinase gene corresponding to ORF10. The chitinase gene had a size of 1761 nt, potentially encoding a protein of approximately 65.6 kDa. The deduced amino acid corresponded to a size of 586 amino acids with a putative 19 amino acid putative signal peptide at the N-terminus. Temporal expression analysis of PrGV chitinase transcript in infected Pieris rapae larvae by both semi-quantitative and real-time PCR revealed significant 75 fold increase after four days of infection followed by decline at the latter stages of infection. In addition, time course induction pattern observed by SDS-PAGE followed by subsequent Western blotting with anti-PrGV chitinase antibody revealed the dissociation of the signal peptide from the intact chitinase. N-terminal sequence analysis further confirmed the exact nature of the mature chitinase depicting amino acid residues just after the signal peptide. Furthermore, immunofluorescence studies indicated strong chitinase-specific signals in fat body cells and epithelial cells associated with integument at four days post infection with its assumed significance as secreted protein, possibly due to the lack of ER retention motif (KDEL) in its sequence. Finally, immunogold labeling and electron microscopy studies reflected

Pieris rapae granulovirus is highly pathogenic to the cabbage butterfly (Pieris rapae), an important pest of cultivated cabbages and mustard crops. It therefore holds significant promise towards exploitation as a potent bio-control agent in the field controlling the pest population. Whole-genome elucidation of the Korean isolate of the granulovirus, reported the presence of a functional granulin gene corresponding to ORF 1 in its genome. Comprehensive studies towards functional characterization of the gene, established that itis composed of 744 nucleotides and encodes a peptide of 247 amino acid residues. It possessed significant homology with AoGV and ClanGV with 87% identity at amino acid level. Multiple alignment data suggests that the C-terminus region of the gene had three different conserved regions. Time-course studies conducted in PrGV infected Pieris rapae larvae revealed a significant upsurge of the transcript (134 fold) at four days post infection followed by a significant decline at the most advanced stages of infection. Anti-PrGV granulin antibody was produced and western blot conducted with the infected larvae further confirmed the induction pattern with a protein of 30K. Immunofluorescent staining showed a granulin-specific signal in fat body and integument of the infected larvae.Granulin-specific signals were noticed two days post infection with the eventual systemic spread of infection to the associated tracheal matrix witnessed at four days post infection. Immunogold labeling and electron microscopic studies further proved the cytopathological effects as the presence of numerous membrane-bound vesicles with nucleocapsids and abruption of intercellular junctions in fat body and hypertrophied cells in the

Cloning and genomic structure of superoxide dismutade-1(sod1) gene from the entomopathogenic fungus, *Cordyceps pruinosa*

Joo Yeon Kim[1], Nam Sook Park[2], Sang Mong Lee[3]

[1]Pusan National University,Korea, Republic of Korea, [2]Pusan National University, Republic of Korea, [3]Pusan National University, Republic of Korea

We have cloned Superoxide Dismutase-1 gene by PCR from the entomopathogenic fungus, Cordyceps pruinosa, and sequenced and analyzed the complete nucleotide sequence and genomic structure of the gene.The SOD1 gene of Cordyceps pruinosa spans 947bp and consisted of 4 exons and 3 introns coding for 154 amino acid residues. The three different introns in length separate exons of 13, 331, 97 and 20bp. The deduced amino acid sequence of C. pruinosa SOD1 showed 95% identity to Beauveria bassiana and Cordyceps militaris. Phylogenetic analysis showed that C. pruinosa SOD1 is placed in the Ascomycota group of fungal clade.

Rehab E. H. Fadwal, Faiza E. E. Salah and Mohammed H. Z. Elabdeen and Elamin M. E. Dept. of Crop Protection,Faculty of Agricultural sciences U. of Gezira, Sudan An experiment was conducted at the U. Of Gezira Experimental farm to evaluate the effects of 10% aqueous leaf and fruit extracts of Basil, (Ocimum basilicum L.), leaf extracts of Sodom's apple, (Calotropis procera Ait) and fruit extract of Coriander , (Coriandrum sativum L.) on Flea beetle Podagrica spp.on okra. The experimental design comprised 16 plots assigned to 4 treatments (replicated 4 times), arranged in a completely, randomized block design. The treatments consisted of spraying okra plants with Basil, Sodom's apple and Coriander 10% aqueous extract or distilled water (control). The efficacy of the extracts was assessed in terms of shot holes in okra leaves i.e., where Flea beetle larvae were alive and feeding. The results indicated that the three aqueous extracts significantly ($P<0.05$) reduced the infestation level by the Flea beetle on okra leaves. Coriander extract resulted in the lowest infestation level by the Flea beetle (mean number of shot holes =630), followed by Rehan (mean number of shot holes=711) and Usher (794) while the control treatment scored 1327 shot holes.

Box 20 2 Agricultural Research Corporation, Wad Medani, Sudan. 3 CIRAD, Montpellier, France. Email: Faizaruba@yahoo Abstract: The Hymenopterous parasitoids, Hemiptarsemus varicornis (Girault) and Opius dissitus (Muesebeck) are associated with the leaf miner, Liriomyza spp., populations in Central Sudan. The effects of Liriomyza trifolii (Burgess) and Liriomyza sativae (Blanchard) reared on common bean, Phaseolus vulgaris, on the development and efficiency of their two parasitoids were studied at constant conditions of temperature, relative humidity and photoperiod. No significant differences were found between parasitism percentage of H. varicornis or O. dissitus on L. trifolii or L. sativae. However, significant differences were found with respect to adult (male and female) life span as well as the number of adult parasitoids emerged of H. varicornis and O. dissitus. The life span of H. varicornis was shorter than that of O. dissitus, but more adults of the later emerged from the pupae than those of H. varicornis which might have accounted for their almost equal parasitism percentages. Also, no significant differences were recorded with regard to the development of H. varicornis on L. sativae reared on four of its host plants. However, parasitism percentage was significantly higher on gourd (Cucurbita moschata) followed by zucchini (cucurbita pepo), haricot bean (Phaseolus vulgaris) and tomato (Lycopersicon esulentium), respectively.

Molecular shift in insecticidal proteins: I. Evidence of beneficial trait deterioration in nematode-symbiotic bacterium complex

Cheng Bai

Chinese Academy of Tropical Agricultural Sciences, China

Entomopathogenic nematodes are used for the biological control of soil pests and associated with mutualistic bacteria, e.g., Heterorhabditis bacteriophora with Photorhabdus luminescens. The nematode infective juveniles penetrate into the host bodies and release the bacteria. Bacteria grow and produce toxins that kill the host. Nematodes reproduce inside insect cadaver, feeding on bacteria. Biochemical study of the mechanism of trait deterioration in nematode-symbiotic bacterium complex at molecular level is crucial to explore novel and improve existing biological agents for better pest control. Serial in vivo culture with foundation population (FP) of mixed H. bacteriophora strain for 16 passages (each passage equals to two or three generations) results in a 30% loss in virulence, the beneficial trait for pest suppression. Protein analysis (1) on the SDS-PAGE reveals that the insecticidal toxin complex protein with a molecular mass of 283-kDa (toxin A, encoded by TcdA1 gene) is unstable at passage 16 and has been cleaved into 90-kDa insecticidal toxin protein subunits, and (2) on the 2-D gel demonstrates that both 330- and 220-kDa insecticidal toxin complex proteins are abnormally cleaved into 90-kDa protein subunits at passage 16, resulting in a apparently reduced amount of 110-kDa insecticidal toxin protein subunits when compared to the corresponding FP. The 90-kDa toxin protein is truncated form of the 110-kDa toxin protein. This result indicates a difference in the cleavage of the insecticidal toxin complex molecules between passage 16 and the FP.

Characteristics of a BT strain with high insecticidal activity

Cheng Bai
Chinese Academy of Tropical Agricultural Sciences, China

Up date, more than fifty thousands of Bacillus thuringiensis (BT) strains or isolates have been collected, but most of them have non insecticidal activity to pests. It is exciting very few BT strains in the world those have a high toxicity to certain of target pests. A new Bt strain (Bt 00-50-5) is isolated , which has a high activity against pests, e.g., 00-50-5 is about 250 times more toxic than HD-1 (The strain is used often for production) against the banded sunflower moth, Cochlis hopes; The LC50 (50% Lather concentration) is 0.5ppm and 0.2ppm for the mixture of spores and crystals from medium scale fermentation product, and for the purified crystal protein against fourth instar larvae respectively. The pure spores have no obvious to the pest with test concentrations, but the pure crystals show a high insecticidal activity. The bacterium also can control Pieris repae and Agrotis segatum pests. The major insecticidal proteins were characterized. The fermentation of the BT 00-50-5 could be completed within 23 hrs and the ratios of the released numbers of spores : crystals are about 1 : 2.5. BT 00-50-5 has a great potation for making commercial biological pesticides.

Chikungunya an alphaviral infection: Emerging threat in urban area of Bangalore, India

Mohammad Nazrul Islam[1], ZulKifle Mohammad [2], Sherwani Amk[3], Ghosh SK[4]

[1]Filaria Hospital&CDC, Bangladesh, Bangladesh, [2]National Institute of Unani Medicine (NIUM), Magad, India, [3]National Institute of Unani Medicine (NIUM), Mag, India, [4]National Institute of Malaria Research (NIMR), Dewanhali, Ba, India

Background: - Chikungunya virus is a rare form of genus alpha virus (Arbovirus), family-togaviridae which is spreaded by Aedes mosquitoes. Fever with erratic, relapsing and incapacitating arthralgia and arthropathy especially in the metacarpho- phalangeal, elbow, shoulder, knee, ankle, metatarsal joints are the prominent diagnostic features of chikungunya fever. Chikungunya fever outbreaks begin during rainy season when vector density becomes peak and temperature and humidity are favorable for survival of the vector. Method:-The study was conducted in J.J.R Nagar, Bangalore which consists of 200 houses and 1200 populations including migrant workers, temporary and permanent dwellers. Out of 200 houses, 162(81%) were surveyed by simple randomization according to Fisher table of random numbers. 140(98.60%) febrile patient's blood samples were collected in a sterile 5 ml disposable single use syringe. The blood samples were distributed into non-heparinized test tubes with proper labeling and transported to the PHI for Chikungunya IgM antibody test by ELISA method. Larvae samples were collected by following standard sampling procedure. Results:-Total 33(23.57%) cases were found positive for chikungunya IgM antibody. 224 larvae samples were collected for the study out of them 51samples were positive for larvae. Out of 51, 37 were positive for Aedes. 12 were positive for Anopheles and 2 were positive for Culex. Conclusion: - Chikungunya is emerging threat in urban area of Bangalore for last few years. The study revealed that elimination of breeding sites is the cost-effective approach to control of emerging chikungunya epidemic

Epiblema strenuana: Challenges for its use as a biological control agent for the invasive plant *Parthenium hysterophorus* in Africa

Andrew John McConnachie[1], Lorraine Wallace Strathie[2]

[1]*Agricultural Research Council, South Africa,* [2]*Agricultural Research Council, South Africa*

The annual weed Parthenium hysterophorus (Asteraceae: Heliantheae) (parthenium), has wide-ranging negative impacts on crop and animal production, biodiversity conservation, and human and animal health in Africa, Asia and Australia. Parthenium is an increasing problem in southern and eastern Africa, causing severe economic losses in some countries. In 2003, South Africa became only the third country globally, after Australia and India, to implement a biological control programme against this weed. Relying on the successful Australian programme, four insect agents and one pathogen were selected and imported into quarantine in South Africa, for evaluation of their suitability for release. Epiblema strenuana (Lepidoptera: Tortricidae) is one of the most widespread, damaging agents that has established on parthenium in Australia. However, this agent was rejected in India as it completed development on the oil-seed crop, Guizotia abyssinica (Asteraceae: Heliantheae), under laboratory conditions. As an introduction of E. strenuana into South Africa will undoubtedly extend beyond the country borders in time, as a matter of responsibility, initial host range testing in South Africa has focussed on determining the susceptibility of cultivars of G. abyssinica, an important native commercial crop in Ethiopia, to this agent. Under no-choice conditions E. strenuana completed development on all selected cultivars of G. abyssinica. However, in the presence of parthenium, no larval development occurred on G. abyssinica. The impact of these results and issues relating to further consideration of E. strenuana as a potential biological control agent for parthenium in Africa are discussed.

The effects of Thai herbal essential oils on the oviposition-deterrent and ovicidal activities of *Aedes aegypti* (Linn), *Anopheles dirus* (Peyton and Harrison) and *Culex quinquefasciatus* (Say)

Siriporn Phasomkusolsil
King Mongkut's Institute of Technology Ladkrabang (KMITL), Thailand

The effect of oviposition-deterrent and ovicidal of seven essential oils were evaluated towards three mosquito vectors, Aedes aegypti, Anopheles dirus and Culex quinquefasciatus. The oviposition activity index (OAI) values of six essential oils namely Cananga odorata, Cymbopogon citratus, Cymbopogon nardus, Eucalyptus citriodora, Ocimum basilicum and Syzygium aromaticum indicated that there were more deterrent than the control whereas Citrus sinensis oil acted as oviposition attractant. At higher concentration (10%) of Ca. odorata (ylang ylang flowers) it showed a high percentage of effective repellency (ER) against oviposition at 99.4% to Ae. aegypti, 97.1% to An. dirus and 100% to Cx. quinquefasciatus, respectively. The results showed that the mean number of eggs were lower in treated than in untreated water. In addition, there was an inverse relationship between essential oil concentrations and ovicidal activity. As the concentration of essential oil increased from 1%, 5% and up to 10% conc., the hatching rate decreased. The essential oil of Ca. odorata at 10% conc. gave a minimum egg hatch rate of 10.4% (for Ae. aegypti), 0.8% (for An. dirus) and 1.1% (for Cx. quinquefasciatus) respectively. These results clearly revealed that the Thai essential oil of Ca. odorata served as a potential oviposition-deterrent and ovicidal against Ae. aegypti, An. dirus and Cx. quinquefasciatus.

Hyperparasitoids and biological control of insect pests: Differential vulnerability of primary parasitoids to obligate hyperparasitism can mitigate trophic cascades

Robert Sicelo Nofemela

ARC-Plant Protection Research Institute, South Africa

Obligate hyperparasitoids are considered an important ecological disturbance to biological control of insect pests, as they develop on primary parasitoids. While studies have traditionally considered direct interactions in simple food webs, an insect pest population can support several primary parasitoid species. Since primary parasitoids that vary in life-history traits can differ in vulnerability to hyperparasitism, it is desirable to establish if unaffected species can take advantage of reduced competition and increase their contribution to parasitism levels thereby mitigating effects of hyperparasitism to biological control. To investigate this question, I monitored populations of Plutella xylostella (Linnaeus), its primary parasitoids and hyperparasitoids on unsprayed cabbage plots at weekly intervals over seven consecutive years. Cotesia vestalis (Haliday) was a dominant primary parasitoid, as it accounted for 78.27% of total parasitism. However, it was a secondary host to three obligate hyperparasitoids: Mesochorus sp., Eurytoma sp. and Pteromalus sp. At low hyperparasitism levels, the higher efficiency of C. vestalis in utilizing younger host larvae limited host availability to other primary parasitoids. But, as hyperparasitism levels increased and its populations declined, populations of Oomyzus sokolowskii (Kurdjumov) and Diadromus collaris (Gravenhorst) increased significantly as they parasitized a greater proportion of available hosts. The ability of unaffected primary parasitoids to increase their contribution to total host parasitism resulted in insignificant influence of hyperparasitism on total primary parasitism and on infestation levels. This study shows that differential vulnerability of primary parasitoids to hyperparasitism can have a stabilising effect on biological control in one host - multiple primary parasitoid systems.

Morphometric, molecular and biological studies of the *Thrips tabaci* Lind. (Thys: thripidae) populations collected from onion and tobacco in Iran

Lida Fekrat[1], Shahab Manzari[2], Parviz Shishehbor[3]

[1]Ferdowsi unversity of Mashhad, Iran, [2]Iranian Research Institute of Plant Protection, Iran, [3]Shahid Chamran university of Ahvaz, Iran

The onion thrips has ability to form biotypes or subspecies in different geographical regions and on different host plants. In this study, 22 populations of this pest were collected from tobacco and onion in 17 provinces of Iran. 24 continuous variables were measured for each specimen on 631 slide-mounted females. The populations were compared using principal component and canonical discriminant analysis .In spite of some overlap,populations collected from tobacco were distinct from those collected from onion.Thrips individuals were projected on the first two principal components, which together accounted for 73.98% of overall variance. Eigenvalues of PC-I and PC-II were 15.81 and 1.20, respectively. The lengh ratio of 4th/7th antennal segments had the highest influence on PC-I. In canonical discriminant analysis, the first two functions contributed most to the separation between populations which together accounted for 98.38% of the total variation in the data. Also, 85.8% of original grouped cases were correctly classified. To assess population genetic structure of T.tabaci , genomic DNA was extracted using DNeasy Tissue and Blood Kit (Quiagene) .The mitochondrial cytochrom oxidase gene, subunit I (COI) was amplified and sequenced using C1-J-1751 and C1-N-2191 primers. The maximum parsimony, maximum likelihood and neighbor joining and bootstrap analyses were carried out using PAUP*. The most-parsimonious tree (length=168, RI=0.9129, CI=0.8631) and other trees obtained from other methods of analysis showed two distinct clades: 1)thrips collected from tobacco and 2) those collected from onion.The robustness of these clades was supported with the bootstrap values of 100% and 91%, respectively.

Study on population dynamics of *Diaphorina citri* Kuwayama (Hemiptera: Psyllidae) in Baluchestan

Behnam Motamedinia[1], Qodratollah Sabahi[2]

[1]Iran Research Institute Plant Protection, Iran, [2]College of Agriculture, University of Tehran, Iran

Asian citrus psyllid, Diaphorina citri Kuwayama (Hem.:Psyllidae) is one of the most serious pest of citrus and is the vector of citrus greening disease. Population dynamism of D.citri was studied in Sarbaz, Rask and Polan, three regions in Baluchestan zone, Iran during 2007-2008. The terminal branches (25cm length) were evaluated and the relation among weather changes (temperature, humidity, rainfall), young flash density population dynamic was determined. Results showed that D.citri was presented throughout the year in studied area. Density of D. citri in regions Sarbaz and Rask was higher than Polan region. Temperature and young flash density showed positive correlation and humidity and rainfall showed negative correlation with population dynamism of D. citri.

Efficacy of organic and synthetic insecticides on the control of cotton pests: The bollworm complex, *Helicoverpa armigera, Diparopsis castanea* and *Earias insulana* for small-scale farmers

Lawrence Nkosikhona Malinga

Agricultural Research Council, South Africa

A study was conducted during the 2006/2007 and 2007/2008 seasons to test different plant extracts for the control of Helicoverpa armigera, Earias insulana and Diparopis castanea larvae on cotton. Tobacco (Nicotiana tabacium), khaki weed (Tagetes minuta), thorn apple (Datura stramonium) and garlic (Allium sativum) were compared with Mospilan® (acetamiprid) and Decis® (Deltamethrin). During the two seasons, Decis® and tobacco treatments had a significant effect on the Helicoverpa armigera and Earias insulana larvae compared to the other treatments. The highest population reduction of Diparopis castanea larvae was observed in the plots treated with Decis®. The Decis® and tobacco treatments showed significant repellent and insecticidal activity against the bollworm complex (i.e. American, red and spiny bollworms). Plots that were treated with Mospilan® and Decis® had significantly higher cotton seed yields during the 2006/2007 and 2007/2008 seasons. Tobacco treatment gave significantly higher yield than the khaki weed, thorn apple and untreated control but did not differ significantly from the garlic treatment. The tobacco and garlic treatments gave lower yields than the Decis® and Mospilan® treatment but did not differ significantly from the Mospilan® treatment. On average Decis® and tobacco treatments exhibited significantly less bollworm larvae than the other treatments. Tobacco was the most promising biological pesticide against American and spiny bollworm larvae. These results suggested that plant extracts can be used as an alternative to reduce the bollworm larvae populations on cotton for small-scale farmers.

Late instar western tent caterpillars thrive on tough mature leaves

Rana M Sarfraz[1], Heather Kharouba[2], Judith H Myers[3]

[1]University of British Columbia, Canada, [2]University of British Columbia, Canada, [3]University of British Columbia, Canada

Spring-active, insect herbivores tend to emerge and begin feeding in synchrony with the budburst of their host plants. If leaf maturation is associated with physical and chemical changes in the leaves, which alter their nutritional suitability, asynchrony in egg hatch and budburst can be detrimental to larval success. This study evaluated the impact of leaf maturation on foliage quality of red alder trees for survival and development of western tent caterpillars (Malacosoma californicum pluviale). Mature leaves were tougher than young leaves. Larval responses to leaf maturation were instar-specific and while the survival and growth of early instars was not influenced by leaf age, fourth instar larvae survived better and developed faster on mature leaves than on young leaves. Overall developmental performance of the later instar larvae was higher on mature leaves. Our findings suggest that more rapid leaf maturation of sun-exposed trees is beneficial to western tent caterpillars and this could explain why they prefer to oviposit on the sunny sides of trees. Year to year variation in spring weather related to sun conditions could potentially modify populations of tent caterpillars by influencing food quality for later instars, but early instar larvae are little influenced by the phenology of leaf development.

Spectrum, stability and durability of monolocus and pyramided lines with green rice hopper [Grh] resistance genes

Vu Quynh

Intenational Rice Research Institute, Philippines

Near Isogenic lines containing either one, two or three loci that code for resistance against the green rice leafhopper (Nephotettix cincticeps)[GRH] were evaluated for their resistance against other leafhoppers and planthoppers. Pyramided lines that contained grh2 and grh6 demonstrated general antixenotic resistance against four different hoppers including the green leafhopper [GLH], zigzag leafhopper (Recilia dorsalis)[ZLH], brown planthopper (Nilaparvata lugens)[BPH] and white-backed planthopper (Sogatella furcifera)[WBPH]; however, antibiotic resistance was effective only against GLH and GRL. This antibiotic resistance was not due to any induced resistance mechanism. Monolocus lines with Grh2, Grh4 or Grh6 had no apparent effect on GLH. Two pyramided lines (Grh2+Grh4, and Grh2+Grh4+Grh6) were highly resistant to GLH by reducing oviposition and survival. However, GLH reared successively on Grl2+Grl4 quickly adapted to the antibiotic resistance, but not the antixenotic resistance. Resistance in the pyramided line grh2+grh4 was stable as the plants aged, but likely caused a yield penalty expressed as lower rice grain weight compared with the recurrent parent lines.

Potential of *Paecilomyces lilacinus* for control of *Anastrepha ludens*

Ricardo Toledo Hernandez
El Colegio de la Frontera Sur, Mexico

Paecilomyces lilacinus is commonly fungi used to control phytopathogenic nematodes and insects, but its effect on fruit flies has not been investigated. We evaluated the pathogenicity of nine strains of P. lilacinus on adults of Anastrepha ludens, a pest that limits the production of citrus and mango in Mexico. To determine the pathogenicity, 8 days-old A. ludens adults were inoculated with a suspension of 1x108 conidia/ml under laboratory conditions. The virulence of two strains, CFFS-A53 and CFF-A60, was determined by estimating the LC50 and LT50 on flies of the same age. To evaluate the effect of infection on fecundity and fertility, flies were inoculated by spraying 15 pairs with a suspension of 1x1010 conidia/ml. It was shown that all strains were pathogenic but showed different degrees of virulence, from 28.8 to 52.4% mortality at 22 days after treatment and LT50 from 18 to 22 days. The LC50 for strains CFFS-A53 and CFFS-A60 was 3.10x102 and 1.48x107 conidia/ml, respectively. The infection of P. lilacinus reduced fecundity and fertility rates at 78.16% and 31.45% (CFFS-A53) and 35.62% and 18.52% (CFFS-A60), respectively. The long lethal times suggest that these strains could be used for horizontal transmission, using infected sterile flies as vectors. Likewise, sublethal effects on fecundity and fertility may contribute to reduce fruit flypopulation growing rates.

Forensic Entomology on the Gauteng Highveld, South Africa

Allison Elizabeth Gilbert[1], Belinda Spillings[2], Lizette Koekemoer[3], Maureen Coetzee[4]

[1]University of the Witwatersrand, South Africa, [2]University of the Witwatersrand, South Africa, [3]University of the Witwatersrand, South Africa, [4]University of the Witwatersrand, South Africa

Forensic entomology utilises arthropods in legal investigations that involve death, neglect and abuse of humans or animals. After death there is a defined succession of arthropods that are attracted to the organism as it decomposes. The two main groups of insects with forensic importance are the Diptera (flies) and Coleoptera (beetles). Within the flies the Calliphora (blowfly) group is the most significant and the most abundant. The larval stages of the flies are very challenging to identify morphologically and where possible, are reared to adults for easier identification. Molecular techniques hold promise for faster and simpler identification of these insects. Species-specific sequence variation on ribosomal DNA (rDNA) is commonly used in molecular identification assays in insect species. The Internal Transcribed Spacer region 2 (ITS2) is a variable region within the rDNA and has been used to differentiate between closely related species. This study aimed to create an ITS2 based identification protocol for forensically important dipteran blowfly species present on the Gauteng Highveld, South Africa. Pig carcasses were used to attract insects which were sampled randomly. DNA extractions were performed on all the samples and the ITS2 regions amplified and sequenced. Based on these sequences, species-specific primers were designed.

Specific activity distribution of acetylcholinesterase and its gene ace2 expression in the bumblebee *Bombus hypocrita* (Hymenoptera: Apidae)

Shudong Luo[1], Xiuli Liao[2], Jialin Liu[3], Jie Wu[4]

[1]Institute of Apiculture, Chinese Academy of Agricultural Sciences, China, [2]Institute of Apiculture, Chinese Academy of Agricultural Sciences, China, [3]Institute of Apiculture, Chinese Academy of Agricultural Sciences, China, [4]Institute of Apiculture, Chinese Academy of Agricultural Sciences, China

Acetylcholinesterase (AChE) plays multiple roles in nerve conduction, and is the target site of organophosphorous and carbamate insecticides. In this study, the spatial and temporal activity of AChE and AChE gene ace2 expression in Bombus hypocrita were investigated. Results indicated that the AChE in the head showed the highest specific activity, 63.55% of the total AChE activities, while the thorax and abdomen 18.44% and 18.01%, respectively. The activity of AChE is in agreement with the relative quantitative expression of ace2 in the different tissues of B. hypocrita. The specific AChE activity of the subcellular organelles was, 42.77% in mitochondria, 23.36% in microsomes, 19.16% in cytoplasmic solution, and 14.43% in nuclei and cell debris. Both the activity of AChE and the relative quantitative expression of ace2 for adults were significant higher than that for larvae and pupae, but no significant difference was found among the adult workers at different ages. The lack of difference in the adults indicates that AchE activity was not significantly different between the foragers and nurses as well.

Keywords:*bumblebee, Bombus hypocrita, acetylcholinesterase, spatial and temporal distribution, ace2*

Improved performance of Azadirachtin and Matrinee insecticides by plant oil for chemical control of the leafminer, *Liriomyza sativae* Blanchard (Dip: Agromyzidae) in cucumber

Ahmad Baghdadi[1], Fatemeh Saberfar[2], Aziz Shaekhi[3]

[1]PayamNoor University, Iran, [2]University of Tehran, Iran, Iran, [3]Ministry of Agriculture, Iran

The leafminer, Liriomyza sativae Blanchard, has become one of the most serious pests in greenhouses of vegetable crops throughout the world because of its short generation time, high reproductive rate, conspicuous damage and the ability to develop resistance to currently registered insecticides. In this study Azadirachtin 15% and kingbo 0.6 % (active ingredient: oxymatrine 0.2% and psoralen 0.4%) has been tested on L. sativae. Also a potent synergistic role of mineral oil with these insecticides was studied. These treatments were conducted on cucumber plants under laboratory conditions (25°c, 65 RH, L: D 16:8). The leaf-dip bioassay method was adopted for assaying azadirachtin and Kingbo as alone or mixed with mineral oil. The LC50 was estimated by POLO-PC, SAS software. The results indicated that the mixture of azadirchtin had a lower LC50 compared with insecticide alone (LC50 of azadirachtin and azadirachtin plus oil were 9.5 and 0.02 ppm respectively), but LC50 of Kingbo alone and Kingbo with oil were 8.86 and 3.13 ppm respictively. Laboratory bioassay showed that toxicity of azadirachtin was significantly increased when it was applied in an oil mixture. Thus, the addition of mineral oil (25%) to azadirachtin and Kingbo concentrations caused to increase the effectiveness of the insecticides and also could reduce up to 50% of insecticide applied dosages.

Sublethal effect of two conventional insecticides on life table parameter of ectoparasitoid *Habrobracon hebetor* (Say) (Hymenoptera: Braconidae)

Ahmad Baghdadi[1], Hassan Morsali[2]

[1]*PayamNoor University, Iran,* [2]*Agriculture ministry, Iran*

This study was performed to assess the effect of some sub lethal concentrations of Indoxacarb and Thiodicarb on life table parameters of H.hebetor (Say). The experiments was assessed at 27± 0.2°c, 65%±10% RH and a photoperiod of 16: 8 (L: D) hours. Our results indicated that in control, the first mortality was occurred after 26 days of appearance, and in other groups ,indoxacarb and thiodicarb, this phenomenon was occur at the days of 8 and 15, respectively. lx in control, indoxacarb and thiodicarb were 49.52, 43.77, and 40.55, respectively. The values of life expectancy (ex) showed the highest between all tested concentrations. In control was 39.46 while this parameter in indoxacarb and thiodicarb were 34.36 and 30.03.The Gross reproductive rate was significantly higher in control, to compare with insecticides treatment. The Intrinsic rate of increase in control was higher than other insecticide treatments. This parameter in control was 0.25573 while in insecticide treatment, Indoxacarb and thiodicarb, were 0.23864 and 0.24707 respectively. Other life table parameter such as finite rate of increase (λ) and net reproductive rate (R0) in control was higher. Mean generation time (Tc) in thiodicarb treatment was lowest and in indoxacarb treatment was the highest. Doubling time (Dt) didn't showed significant differences at all tested concentartions.

The Laelapidae is a large family of worldwide distribution. Many of its species are ectoparasite of mammals, arthropods and birds. Some of laelapid mites are free living predators in soil habitats. During 2010-2011, they were collected and identified in soil and plant debris of apple orchards of Salmas region in West Azarbaijan Province. The mites were extracted with a Berlese/Tullgren funnel. They were cleared in Nesbitt's solution and were mounted in Hoyer's medium on microscope slides. In this study, 14 species were identified. Among them, four species were new for West Azarbaijan Province fauna and one species was new record for Iran. They were marked with one and two asterisks as follows: 1- Androlaelaps casalis (Berlese, 1887) 2- Euandrolaelaps karawaiewi (Berlese, 1903) 3- Eulaelaps stabularis (Koch, 1839) 4- Cosmolaelaps near gladii (Karg, 1993) 5- Cosmolaelaps lutegiensis* (Shcherbak, 1971) 6- Cosmolaelaps vacua (Michael, 1891) 7- Gaeolaelaps aculeifer (Canestrini, 1883) 8- Gaeolaelaps nolli (Karg, 1962) 9- Gaeolaelaps queenslandicus (Womersley, 1956) 10- Laelaspis missouriensis* Ewing, 1909 11- Ololaelaps sellnicki** Bregetova & Koroleva, 1964 12- Pneumolaelaps asperatus (Berlese, 1904) 13- Pneumolaelaps linteyini* (Smasinak, 1964) 14- Pneumolaelaps lubrica* Voigts & Oudemans 1904

Effects of silver nanoparticles (Ag NPs) and polymers on stored pests for improving the industry of packaging foodstuffs

Somaye Allahvaisi

Islamic Azad University, Sanandaj Branch, Young researches Club, Kurdistan, Iran

Changes in agricultural technology have been a major factor shaping modern agriculture. Nano-silver is used in an increasing number of products. The customers`s complaints of the contaminations of foodstuffs to stored pests such as insects, mold and toxic fungi polluted packagings after a short time of storing, were reasons to perform this research. Cereals are one of the most important stored products. Microflora of wheat, corn, barley seeds mostly consists of bacteria, actinomycetes and fungi genera specially Aspergillus spp as amounts of aflatoxin B1 were detected in much cereals packaged. In this work, we conducted batch experiments to assess the efficiency of silver nanoparticles incorporated into packaging polymer on the growth of fungi and insect pests. Sitotroga cerealella Ol. (Lep.: Gelechiidae) is tested because of economical importance of this pest in storing`s industry of packaged cereals. Then, we applied Ag Nps on the best packaging polymer (PP). The results showed that not only Ag Nps could optimally omit toxic pathogens but also have a toxicant effect for insects. Thus, in this study the property of anti microbial and toxicity of Ag Nps as a non-chemical pesticide investigate in the terms of storing cereals foods. This study helps the health of foodstuffs after packaging until consuming.

The investigation of different polymers resistance against penetration of *Rhyzopertha dominica* F. (Col. Bostrychidae) and CO2 gas

Somaye Allahvaisi

Islamic Azad University, Sanandaj Branch, Young researches Club, Kurdistan, Iran

In response to on-going consumer complaints regarding insect infestation of cereals-based packaged products kept at warehouses, research was undertaken. In order to the significance of cereals in feeding humans and the great application of polymers in packaging of these crops, we investigated the current polymers in market. Contaminated grains with lesser grain beetle adult released in around of the prepared packages with three kinds of transparent and flexible polymers followed: PE, PP and Cellophane in two thickness of 16.5 and 29 µm and so, determinate the permeability rate of polymers to this pest. The tests repeated 5 times and the means compared with MSTATC software and T-student test with 0.05-error level. Results showed that ten days after initiation of experiment the insects could create many punctures in the PE packages with thickness of 16.5 µm and the crop contamination was 100%. Whereas, pollution did not occur in no thicknesses of PP packages, at all. Comparing the means showed that difference of pest penetration percentage and crop contamination inside other polymers was significant in probability level 5%. So, PE with 16.5 µm thickness was worst polymer for packaging. In the other hand, because of great using fumigants for killing pests inside packages in stores, the used polymer for packaging in addition of protection of the crops, should be permeable to gases. Therefore, these polymers permeability to Co2 gas studied. The results showed that the polymers permeability to Co2 gas follow: Cellophane>PE>pp and the resistance of them against pest attack follow: PP>Cellophane>PE.

Study of different polymer coverings for reducing the contaminations of cereals packagings in stores

Somaye Allahvaisi

Islamic Azad University, Sanandaj Branch, Young researches Club, Kurdistan, Iran

With regard to ever-increasing growth of crowd, keeping and protecting of stored products and raising of expiration longevity of them is the most important problem for our in future. In food industry, packaging is one of important factors in protection of quality and safety food. Prepared packaging from three transparent and flexible polymers PE, PP and Cellophane with 2 thicknesses of 16.5 and 29 µ, used for foodstuffs packaging. Insects of Tribolium castaneum Herbst. (Col: Tenebrionidae) and Sitophilus granarius L. (Col: Curculionidae) are contaminated serious pests in storages of cereals. With regard to development stages of infested in storages adult or larvae of these insects as target pest, located in manufactured package by mentioned polymers with flour and kernels and determinated permeability balance of polymers with different thicknesses to this pest. Each test had five replications. Means of penetration rates were compared by T-test at 5% level. Results showed that twenty days after initiation of experiment average of permeability rates to PE polymer with 16.5 µm thickness had the most permeability against the tested pests, as the product was completely infested and a lot of punctures were created in them by insects. So, PE was known moat unsuitable packaging polymer. PP was the best packaging polymer because no penetration was observed in the thicknesses of so, this polymer. Comparison of the means indicated that there was a significant difference between contamination rates of products inside the used polymers and their thicknesses ($p \leq 5\%$). To sum, the results showed that

Application of microwave radiation for controlling Tobacco beetle and studying packaging polymers to preserve cereals

Somaye Allahvaisi

Islamic Azad University, Sanandaj Branch, Young researches Club, Kurdistan, Iran

Despite application of protectant insecticides and fumigants, we observe the contamination of agriculture products in stores. Therefore, it is necessary to use a novel and suitable alternative control method. Developmental stages of Lasioderma serricorne F. including egg, larvae, pupa and adult were exposed to microwave radiation (2450MHZ) at power level of 150W with exposure times of 720, 420, 240, 120 Sec and with power level of 300W, and times of 100, 70, 40, 25Sec were for each developmental growth stage, separately. Experiments were carried out in complete randomized design with five replications and comparing mortality means was conducted in Duncan test with 0.05-error level. The mortality was determined at known intervals every day. The results showed that there was a relationship between constant power and exposure time. Complete mortality for eggs gained at 300W and 100Sec. Last instar larvae were controlled by 300W at 40Sec and for pupae, 150W at 420Sec were sufficient for not produce adults. In the case of adults, complete mortality was obtained by 300W at 70Sec. In these experiments, pupa was the most vulnerable and egg was the least susceptible. Therefore, 300W and 100Sec was sufficient for controlling all developmental stages of this insect. Radiation for disinfestations is effective when suitable packaging materials pack the product. PP was the best packaging material because the insect wasnot able to puncture it and created infestation. The most unsuitable packaging was Cellophane because

Estimating of phosphine (PH3) gas effective quantities on different development stages *Plodiainterpunctella* (Hb.) in passing from nut packages in store

Somaye Allahvaisi

Islamic Azad University, Sanandaj Branch, Young researches Club, Kurdistan, Iran

Sub lethal doses cause to resistant the pests in short times. Therefore, determining values of used pesticides in stores is serious that these are able to pass packaged materials and to fumigant the products inside packaging. This pest in addition of high damage in stores, caused the favorable conditions for attack and growth of pathogenic agents as example fungi that many of them infected the foodstuffs with secretion of toxic materials such as aflatoxine, severely and create dangerous diseases on human and livestock such as cancers. Therefore, challenging to this pest is important from agriculture and sanitation aspect. In this research, we place 15 gr of infected nuts with three different development stages of Indian moth (egg, 9 days old larvae and adult) inside polymeral packages of PP (suitable for packaging in stores). Fumigation was conducted by use of aluminum phosphide tablets 56% in vacant air steel tanks. The tests repeated five times in 5 treatments with control test. After 72 hours, the mortality accounted. The obtained data was analyzed using probit procedure of SPSS10 software. Under these conditions, the respective LC50 and confidence limits values to kill 50% of inoculated eggs, larvae and adult were 36.54(27.5?48.8), 8.75 (6.5-11.6) and 3.9 (2.9?5.14) mg Al/L, respectively. The most mortality was for 417.85 mgL-1 concentration. In conclusion, the results demonstrated that eggs were more resistant than larvae and adults in this species and those adults were the most susceptible stage. Also, the best stage of combating with Indian moth is adult stage.

The investigation of protein effects on fertilization *Tribolium castaneum* (Col.: Tenebrionidae) in wheat stores

Somaye Allahvaisi

Islamic Azad University, Sanandaj Branch, Young researches Club, Kurdistan, Iran

Proteins are one of the most important sources created energy in insects' body cells. Studying this matter how much of protein affect on pest population is serious. In this research, we separate the female and male adult insects of Tribolium castaneum Herbst. and added some creatine to indispensable wheat flour for insect feeding at 19:1, 14:1, 9:1 and 6:1 ratios. The tests repeated five times and did for seven continuous generations in warehouse at 25±5°C with 70% Rh and with control test (without decrease or increase of protein). Means compared by in MSTATC software, Dancan test with 0.05-error level. The results showed that at 6:1 ratio from the wheat flour-creatine compound, decreased fertilization and population growth significantly ($p \leq 5\%$) in 7th generation to ½ of 1th generation so much that sometimes did not lay any egg. Finally, this research carried out on the wheat grains had 14% loss of sunn pest and their protein was lost. In order to the results, needed protein for red flour beetle cause proper activity but too increasing of its caused toxicity and deduction of progeny. So, fertility rate and population growth rate (rm) of one species of stored-pest depended on the compounds percent of formed foodstuffs. Thus on basis of protein value, rm increase of T. castaneum followed: well wheat>wheat with decreased protein>wheat with increased protein.

Oral toxicity of entomopathogenic symbiotic bacterium *Photorhabdus temperata* against various insects and nematodes

Md Asaduzzaman[1], Yam Kumar Shrestha[2], Jun-Young Ahn[3], Jae-Kyoung Shim[4], Young-Jin Lee[5], Kyeong-Yeoll Lee[6]

[1]Kyungpook National University, Republic of Korea, [2]Sankhuwasava, Department of Agriculture, Nepal, [3]College of Agriculture and Life Sciences, Kyungpook National University, Daegu, 702-701, Republic of Korea, [4]Kyungpook National University, Republic of Korea, [5]Ecowin co. Ltd., Daegu, Republic of Korea, [6]Kyungpook National University, Republic of Korea

Photorhabdus temperata is a symbiotic bacterium that mutually associated with entomopathogenic nematode Heterorhabditis. The oral toxicity of 5 P. temperata strains collected in different regions of Korea was determined in the in the immature and mature stages of various insects and nematodes. When diet or water containing culture media containing 1 of the 5 different strains was ingested by immature insects, the first instar larvae of both Galleria mellonella and Lucilia caesar and young larvae of Culex pipiens pallens died within 3-5 days after treatment. Particularly, a fraction separated by ethyl acetate was highly toxic to C. pipiens pallens nymphs. However, mortality of Plodia interpunctella neonate larvae was slightly slower and reached 94.4%-100% within 7 days after treatment. The mortality rate of a control group given a diet containing water, the medium without cultured bacteria, or Escherichia coli culture medium was not affected. The oral ingestion of sucrose diet solutions (20%) containing supernatant of the Photorhabdus culture media was completely lethal at 60 h after treatments. In addition, ingestion of Photorhabdus culture media significantly inhibited molting of third instar Plodia larvae and fecundity of a katydid, Paratlanticus ussuriensis. Soil treatment of Photorhabdus culture medium was lethal to a rootknot nematode, Meloidogyne arenaria, and inhibited rootknot formation in cucumber and tomato plants. Our results suggest that the oral administration of Photorhabdus bacterial medium was highly lethal to immature insects and also toxic to the development and reproduction of various insects.

Evaluation of *Solenostemma argel* extracts for their potential larvicidal activities against *Anopheles arabiensis* Patton (Diptera: Culicidae)

Amal Elsayed Edriss[1], Abdalla Abdelrahim Satti[2], Zuhair Alfadel Alabjar[3]

[1]Environment and Natural Resources Research Institute, Sudan, [2]Environment and Natural Resources Research Institute, Sudan, [3]Environment and Natural Resources Research Institute, Sudan

Among the prevalent mosquito species in Africa Anopheles arabiensis is the important malaria vector distributed in most countries. The main control tactics adopted depend largely on the application of synthetic chemicals. However, the socio-economic and environmental drawbacks of these chemicals are well known in everywhere. Therefore, this work was proposed to study the occurrence of A. arabiensis in central semi arid region of Sudan, and to evaluate different extracts of Solenostemma argel on its control. Leaves and seeds of the plant were extracted using water and organic solvents (viz., petroleum ether and ethanol), and their phytochemical constituents were analyzed. Bioassays of such extracts were conducted against the 4th instar larvae of the mosquito, where the mortality and residual effects were compared. The results revealed that the relative occurrence of A. arabiensis were higher around the River Nile. The chemical constituents of the tested extracts showed variable levels of secondary metabolites, i.e., alkaloids, saponins, flavones, flavonoids, amino acids, triterpenoids and sterols. The highest mortality percent (90%) was achieved by the seeds petroleum ether extract (LD50 1000ppm), which was comparable with that of the standard insecticides (Malathion and Abate) used. This extract also gave the best residual activity after one month. However, the mortality means of different botanical treatments increased with increasing concentrations and time of exposure. In conclusion, the findings proved the potent insecticidal activity of S. argel against A. arabiensis, and suggested more studies to be utilized commercially as natural mosquito larvicide.

Effects of thiamethoxam on feeding and tunneling activities of the termite Microcerotermes diversus Silvestri (Isoptera: Termitidae) under laboratory conditions

Zeinab Sarah Fathollahi
Shahid Chamran University of Ahwaz, Iran

Treating soil with insecticides is thought to be an effective method for termite control. Speed of action and repellency of insecticides are important factors for discussing their barrier effects as soil-treatment termiticide. Microcerotermes diversus (Silvestri) is the most economically destructive termite in structures in Ahwaz region, because the species feed on anything with cellulose. M. diversus live in subterranean nests and access to buildings and plants through subterranean galleries. The chemical barrier effect of thiamethoxam against M. diversus was evaluated under the laboratory using glass tube and plastic container methods. The concentrations used ranged from 5 to 5000 ppm. Soil treated with >50 ppm of thiamthoxam had a barrier effect and could stop the penetration of termite within 7days. Thiamethoxam did not act as a repellent, as indicated by a gradual increase in mortality at >50 ppm with slight penetration, tunneling area and feeding activity into the treated soil during the 7-day trial. The results suggest that thiamethoxam is an effective termiticide, a suitable barrier for soil treatment, that also acts as a non-repellent, inhibitive entry of termites into treated soil.

Transfer of thiamethoxam from exposed to non-exposed workers of *Microcerotermes diversus* Silvestri (Isoptera: Termitidae)

Zeinab Sarah Fathollahi
Shahid Chamran University of Ahwaz, Iran

Because Microcerotermes diversus (Silvestri), a subterranean termite, is able to attack cellulosic materials, is destructive to structures, and is the most economically important wood pest in Iran. Therefore, control or management of the termite is of serious public concern. The use of nonrepellent termiticides such as thiamethoxam (a neonicotinoid compound) has been gaining popularity in recent years. The success of these compounds in managing termite infestations depends primarily on their speed of action and non-repellent characteristics. The current study was designed to determine termite mortality, non-repellency, and horizontal transfer of termiticide by trophallaxis when termites were in contact with treated-filter paper in laboratory choice and no-choice tests. A donor-recipient trial in two ratios was used: 1:1(10 donors: 10 recipients) and 1:5 (10 donors: 50 recipients). In one trial, workers were placed on filter paper previously treated at 5.0, 10.0 or 15.0 ppm thiamethoxam. Exposed workers were then removed from the treated paper, placed in a clean container, and then allowed to have side-by-side feeding interactions with previously non-exposed recipient workers for 14 days, after which mortality was assessed. Results indicated that mortality of non-exposed workers contacted by the exposed workers increased with increasing insecticide concentrations in both donor-recipient worker ratios. Therefore, transfer of lethal insecticide concentrations from the donor to recipients was observed with thiamethoxam.

Differential response of male and female adult banana weevil, *Odoiporus longicollis* Olivier (Coleoptera: Curculionidae) to fresh and rotten host cues

Kamala Jayanthi Pagadala Damodaram[1], Vivek Kempraj[2], Ravindra Aurade[3], Abraham Verghese[4]

[1]Indian Institute of Horticultural Research, India, [2]Indian Institute of Horticultural Research, India, [3]Indian Institute of Horticultural Research, India, [4]Indian Institute of Horticultural Research, India

The banana pseudostem weevil, Odioporus longicollis Olivier (Coleoptera: Curculionidae) is an economically important pest in South East Asia limiting the production of banana. The pseudostem becomes weak and starts rotting, leading to break down upon infestation. Management practices to control the damage caused by weevil vary widely from regular application of chemical insecticides, cultural practices and biological control. Attempts to control this monophagous weevil through methods involving semiochemicals merits more attention as they provide selective control. In our search for an effective phyto-semiochemical from host plant, banana, an interesting sex linked differential response of weevils to banana volatiles was noticed. Y-tube bioassy was carried out to confirm this preference. When the host volatiles were compared with control, male and female weevils exhibited preference for both fresh and rotten stem volatiles. However, in choice bioassay, the female adult weevils showed a clear preference for rotten stem volatiles and males to fresh stem volatiles showing a clear sex linked preference for host cues. Further studies to identify the responsive chemical fraction that elicited response were identified through GC-EAD and GC-MS.

Keywords:*GC-MS, GC-EAD, Odoiporus longicollis, volatiles, banana*

The Brinjal fruit and shoot borer, Leucinodes orbonalis Guenee (Pyralidae: Lepidoptera) is one of the major insect pest on cultivated brinjal (Solanum melongena L.) causing heavy fruit loss. In the present study, attempts were made to understand the role of trichome based host-plant resistance to L. orbonalis mainly in different wild cultivars of Solanum viz., S. macrocarpon, S. indicum, S. viarum, S. torvum, S. ethiopicum, S. mammosum, S. gilo compared to cultivated S. melongena. A total of eight types of glandular and non-glandular trichomes were observed in wild as well as cultivated Solanum species. There is difference in the total number as well as types of trichomes present in adaxial and abaxial surface of brinjal leaves. The stellar trichomes were found to be abundant in S. melongena, S. indicum and S. gilo. Whereas, in S. mammosum and S. viarum Type I - Type VII trichomes were also present besides stellar trichomes. Laboratory bioassays were also carried out to study the influence of these trichomes on neonate larvae of L. orbonalis. In, S. mammosum and S. viarum, maximum larval mortality was observed within 4?6 h after larval release compared to other cultivars where it was found to be up to 10?12 h. The entrapment of larvae was also found to be very high in S. mammosum and S. viarum compared to other cultivars. However, the initial repellency was observed to be high in S. indicum, S. torvum and S. gilo. The glandular trichome exudates may be playing important role in causing

Whitefly resistance in tomato

Floor van den Elsen[1], Sjaak van Heusden[2], Colette Broekgaarden[3], Marcel Dicke[4], Ben Vosman[5]

[1]Wageningen UR, Netherlands, [2]Wageningen UR, Netherlands, [3]Wageningen UR, Netherlands, [4]Wageningen UR, Netherlands, [5]Wageningen UR, Netherlands

Whitefly resistance is a much desired trait in tomato growing. An F2 population was studied for resistance against whitefly Bemisiatabaci by analyzing phenotypic and metabolic traits. Multivariate statistical analyses revealed that a large complex of metabolic components was associated with whitefly resistance and a smaller number of metabolites were associated with whitefly susceptibility. Minor QTLs were identified for whitefly phenotypic parameters and metabolic constituents that associated with whitefly resistance and susceptibility. In an F2BC1 population we observed that some genotypes were still completely resistant against whiteflies, but the complexity of metabolic profiles was strongly reduced and only a selection of resistance-related constituents was present. A QTL analysis of metabolic constituents associated with whitefly resistance revealed the presence of metabolic QTLs that co-localize with whitefly phenotypic QTLs. Plant morphologic characteristics were studied and a positive correlation was found between the presence of type I and IV glandular trichomes on the leaf surface and reduced vitality and oviposition of the whitefly. In addition, it was observed that the presence of type I and IV trichomes was positively correlated.

Toxicological potential of peel extract of *Citrus limon* against *Tribolium castaneum, Sitophilus granarius* and *Cryptolestes ferrugineus* under laboratory conditions

Fawad Zafar Ahmad Khan[1], Muhammad Sagheer[2], Mansoor ul Hasan[3], Kazam Ali[4], Jaffar Hussain[5]

[1]University of Agriculture, Faisalabad, Pakistan, Pakistan, [2]University of Agriculture, Faisalabad, Pakistan, [3]University of Agriculture, Faisalabad, Pakistan, [4]University of Agriculture, Faisalabad, Pakistan, [5]University of Agriculture, Faisalabad, Pakistan

Laboratory experiments were conducted so as to evaluate the effectiveness of Citrus limon peel extracts on Tribolium castaneum, Sitophilus granarius and Cryptolestes furragenius. Experiments were successfully completed in the Stored Grain Pest Management Cell, Department of Agri. Entomology, University of Agriculture, Faisalabad. The toxicological potential of peel extracts was evaluated at different exposure periods. Three concentrations (5, 10 and 15 %) of the C. limon peel extract were used and results were evaluated after different exposure periods (24, 48, 72, 96, 120, 144 and 168 hours). Residual method was used in the experiment to determine the contact toxicity of peel extract. The results showed that C. furragenius showed the best response followed by S. granarius and T. castaneum, respectively. Overall C. furragenius showed 93.01%, 69.78% and 61.96% mortality, S. granarius showed 55.57%, 35.835% and 28.21% and T. castaneum showed 23.53, 16.77, 16.47% mortality at 15, 10 and 5% of concentrations, respectively. C. furragenius showed the maximum mortality of 100% at 15% concentration in 120h exposure. S. granarius showed 95.68% mortality at 15% concentration in 168h exposure whereas T. castaneum showed a maximum of 64.02% mortality at 15% concentration in 168h exposure. The LC50 values were also calculated according to Probit analysis method. After an exposure of 7 days, the results were evident that acetone peel extracts of C. limon has a strong potential to control primary as well as the secondary pests of stored grains and can serve as an eco-friendly bio-pesticide.

Phytochemical analyses of five sudanese plants for their constituents of biologically active compounds

Abdalla Abdelrahim Satti[1], Amal Elsayed Edriss[2]

[1]Sudan Academy of Science, Sudan, [2]Sudan Academy of Science, Sudan

Higher plants are known to contain several types of secondary metabolites with profound biological activities. Such plant derivatives represent untapped sources for unlimited applications in public life and industry. Due to their diversified structural compounds, they also provide new models to produce chemical analogues with enhanced potencies and/or utilities. In agriculture, numerous plant extracts were proved significant effects in controlling different pests and diseases; hence some commercial pesticides were formulated from certain botanical compounds. In this research, phytochemical analyses of five indigenous plants were investigated. These plant species and their studied parts included; Citrus paradisi (leaves & seeds), Calotropis procera (leaves & flowers), Eucalyptus camaldulensis (leaves & fruits), Ocimum basilicum (leaves & seeds) and Ricinus communis (leaves & seeds). Three extracts (aqueous, ethanol and petroleum ether) were analyzed from each plant to ascertain their active chemical groups of non polar and polar components. The results of water extract showed that alkaloids, saponins, flavonoids and flavones are the main chemical groups present in all plants at variable levels. Moreover, traces amounts of sterols and triterpenes were detected in seeds of R. communis. However, ethanol extract was dominated by triterpenoids, alkaloids and sterols, and to some extent flavonoids and flavones. On the other hand, petroleum ether extract yielded principally triterpenoids and sterols. Since these plants are available in the country and having many traditional uses, particularly in medicine and pest control, the current research explained that promising active ingredients could be obtained from them for proper commercial and industrial exploitation.

Courtship and mating behaviors of *Phyllotreta striolata* (Fabricius) (Coleoptera, Chrysomelidae)

Hualiang He[1], Shuying Bin[2], Jintian Lin[3]

[1]Zhongkai University of Agriculture and Engineering, China, China, [2]Zhongkai University of Agriculture and Engineering, China, China, [3]Zhongkai University of Agriculture and Engineering, China

Phyllotreta striolata (Fabricius) is one of the destructive pests to cruciferous crops worldwide. By employing real-time shooting techniques, the characteristics of courtship and mating behaviors between male and female adults were analyzed. Specifically, we found that the courtship behavior cost no more than 10 seconds and its frequency showed an increasing trend after 15:00:00 PM. However, this mating behavior, which lasted generally from 13 to 15 minutes, had a low frequency that was only once or twice per day. In addition, there was no correlation between the accomplishment of mating behavior and the multi-frequency of preludiously successional courtship behavior.

Fumigasion and packaging integrated effects for reducing *Callosobruchus maculates* F. (Col: Bruchidae) contaminathions in stores

Somaye Allahvaisi

Islamic Azad University, Sanandaj Branch, Young researches Club, Kurdistan, Iran

Protection of stored gricultural products such as grains in bages because of its warps make it possible to penetrate the pest insects. Prepared packages from three transparent and flexible polymers including; PE, PP and Cellophane with 2 thicknesses of 16.5 and 29 µ.m., used for grains packaging. Adult insects of Callosobruchus maculatus F. (Col: Bruchidae), as target pest, located around of manufactured package by mentioned polymers with grains and determinated polymers permeability to this pest. Each test had five replications. Means of penetration rates were compared by MSTATC and T-test at 5% level. Results showed that nine days after initiation of experiment average of permeability rate to cellophane polymer (16.5 µ.m. thickness) was %10±0.2. While no penetration were observed in PP polymers. Comparison of the means indicated that there was a significant difference between permeability and contamination rates of products at different polymrs and thicknesses ($p \leq 5\%$). Therefore, cellophane was less suitable polymer for packaging of foodstuffs. On the one hand, when suitable packaging for control of pest is efficacious that products placed inside package is none contamination. Thus, permeability to Phosphine gas (PH3) in packaging was considerated.

Efficacy assessment of *Isaria fumosorosea* and SilicoSec against *Tribolium castaneum*, *Rhyzopertha dominica*, *Cryptolestes ferrugineus* and *Liposcelis paeta*

Waqas Wakil[1], Muhammad Yasin[2], Yong Jung Kwon[3], Tahira Riasat[4], M. Usman Ghazanfar[5], Mirza Abdul Qayyum[6]

[1]Universsity of Agriculture, Pakistan, [2]University of Agriculture, Pakistan, [3]Kyungpook National University, Republic of Korea, [4]Universsity of Agriculture, Pakistan, [5]University College of Agriculture, University of Sargodha, Pakistan, [6]University of Agriculture, Pakistan

The present research was aimed to evaluate the insecticidal efficacy of entomopathogenic fungi, Isaria fumosorosea and diatomaceous earth formualtion SilicoSec against four species of stored grain insect pests; Tribolium castaneum (Herbst) (Coleoptera: Tenebrionidae), Rhyzopertha dominica (F.) (Coleoptera: Bostrychidae), Cryptolestes ferrugineus (Stephens) (Coleoptera: Laemophloeidae) and Liposcelis paeta (Pearman) (Psocoptera: Liposcelididae). The fungus was admixed with wheat grains at 1.7×106 and 1.7×108 conidia kg-1 individually and with 200 ppm of SilicoSec. The tests were conducted at 30±1oC and 65±5% rh. The adult mortality of the exposed insects was measured after 7, 14 and 21 d of exposure. The mortality for all the insects treated with the highest dose of I. fumosorosea with SilicoSec was significantly higher than the alone treatments. The mortality was increased with exposure interval and increased dose rates. The rate of mycosis and sporulation in the cadavers of all the insects was higher where the I. fumosorosea was applied at low dose rates.

Evaluation of biocontrol agents for the control of fruitborer *Helicoverpa armigera* (Hubner) in the fields of tomato crop

Waqas Wakil[1], Muhammad Tahir[2], Yong Jung Kwon[3], M. Usman Ghazanfar[4], Mirza Abdul Qayyum[5], Tahira Riasat[6]

[1]University of Agriculture, Pakistan, [2]University of Agriculture, Pakistan, [3]Kyungpook National University, Republic of Korea, [4]University of Agriculture, Pakistan, [5]University of Agriculture, Pakistan, [6]University of Agriculture, Pakistan

The study was conducted to assess the efficacy of various biorational microbial pesticides, Beauveria bassiana (1.3x108 conidia/ml), HaNPV (2.5x107 POB/ml), Deodonia viscose (7 ppm), new chemistry Coragen (99 ml/ha) and their possible combinations against Helicoverpa armigera Hubner (Lepidoptera: Noctuidae) on tomato crop under various ecological conditions. The treatments were sprayed twice, the data on larval population, percent fruit infestation, population of natural allies and yield of tomato fruits were recorded. The treatments showed significant difference, however, the application of HaNPV+Coragen showed maximum control of pest followed by B. bassiana+Coragen and the insecticide treatment alone. However, the minimum pest control was recorded in those plots where plant extract was sprayed, the percent fruit infestation in all the six pickings differs significantly among treatments. The application of HaNPV+Coragen showed minimum pest infestation and was at par with those plots where B. bassiana+Coragen were sprayed. The application of plant extract showed maximum fruit infestation and did not proved an effective treatment. The results clearly indicated that the microbial insecticides may provide better control of the insect pests without harming the natural allies and the ecosystem.

Demographic parameters of cowpea aphid, *Aphis craccivora* (Homoptera: Aphididae) reared on botswana cowpea landraces

Motlalepula Machacha[1], Motshwari Obopile[2], Aobakwe Boyce Tshegofatso[3], Chiyapo Gwafila[4], Mapena Ramokapane[5]

[1]Botswana College of Agriculture, Gaborone, Botswana, [2]Botswana College of Agriculture, Gaborone, Botswana, [3]Botswana College of Agriculture, Gaborone, Botswana, [4]Botswana College of Agriculture, Gaborone, Botswana, [5]Botswana College of Agriculture, Gaborone, Botswana

The variation demographic parameters were used to assess resistance of cowpea landraces against of the cowpea aphid (Aphis craccivora Koch). The cowpea landraces were B 261-B, B 383, B 013-F, B 339 and susceptible variety blackeye was included as a check. The demographic parameters studied were survival and fecundity, intrinsic natural rate of increase, pre-reproductive period and relative growth rate of cowpea aphid. The demographic parameters of A. craccivora differed significantly among varieties supporting our prediction that cowpea landraces resistant to cowpea aphid would have significant effect demographic parameters of the aphid. We observed significantly lower survival, fecundity, intrinsic natural rate of increase and relative growth rate on landraces B261-B and B 383 compared to other landraces. A significant delay in pre-reproductive period was also observed on B261-B and B 383. The results showed that landrace B261-B and B 383 have increased level of resistance as shown by delayed pre-reproductive and reduction in population growth rate, survival and fecundity. This information will be used in the characterization of the landraces before been incorporated in the breeding programme in Botswana.

Effects of levels of initial infestation on damange to registant and susceptible cowpea by *Callosobruchus maculatus* (Fab.)

Jacobs Mobolade Adesina[1], Tom I. Ofuya[2], Joy Idoko[3]

[1]Rufus Giwa Polytechnic, Nigeria, [2]Federal University of Technology, Nigeria, [3]Federal University of Technology, Nigeria

Cowpea cultivars Ife Brown and IT84S-2246-4 were screened for resistance to Callosobruchus maculatus (F.) attack using different insect densities. The number of eggs laid on the seeds, number of seed bearing eggs and seed without eggs, mean number of eggs per seed, number of F1 progeny, number of seed with holes and seed without holes, mean number of seed with hole and developmental time increased as insect population increases. Significantly, more eggs were laid on the seed of Ife Brown (Susceptible cowpea variety) than IT84S-2246-4. However, low adult emergence and high development period were observed on IT84S-2246-4 indicating clear cultivar difference at all insect population. The assessment of the first filial generation (F1 progeny) of the two varieties showed further, that oviposition reduced in insect that emerged from IT84S-2246-4 (resistant variety) when reared on Ife Brown cowpea seeds. Irrespective of cowpea varieties used in the experiment, egg laid and adult emergence by C. maculatus significantly increased with increase in insect density.

Diversity of non-target insect community in bt and non-bt cotton

Anjum Suhail[1], Muhammad Arshad[2], Zain ul Abdin[3], Muhammad Dildar Gogi[4], Rashid Rasool Khan[5]

[1]University of agriculture Faisalabad, Pakistan, [2]University of Agriculture Faisalabad, Pakistan, [3]University of Agriculture Faisalabad, Pakistan, [4]University of Agriculture Faisalabad, Pakistan, [5]University of Agriculture Faisalabad, Pakistan

Cotton crop hosts a rich diversity of insect predators and parasitoids, which have the significant role in regulating the pest population. Bt cotton can alters the insect diversity especially predators and parasitoids by reducing the abundance of target lepidopterous species. A field study was planned for two cotton seasons to compare the non-target insect diversity among transgenic Bt-cotton and non Bt cotton under sprayed and unsprayed conditions. The experiments were conducted at Postgraduate Agriculture Research Station (PARS), Faisalabad, Punjab, Pakistan. A variety of sampling methods were used including sweep net, drop cloth and pitfall trap. The collected insect fauna were identified and further grouped into four categories: non-target pests, beneficials (predators and parasitoids), pollinators and visitors (non cotton insects). The results indicated significant differences in the abundance and species richness of insect community and sub-communities (pests, beneficials, pollinators and visitors) among the treatments across each sampling techniques (sweep net, drop cloth and pitfall) during both years. The insecticide applications significantly reduced the abundance and species richness in sprayed plots of Bt and non-Bt cotton but no significant differences were found between unsprayed Bt and non-Bt cotton, which showed that Bt cotton has no adverse affects on the abundance and richness of non-target insect community and sub-communities. The diversity indices (species diversity and evenness) were generally higher in sprayed plots of Bt and non-Bt cotton. The differences in diversity indices among the varieties in sprayed and unsprayed conditions showed that insecticide application had adverse effects on rare species.

Studies on aphid pests of apple in orchards of Himachal Pradesh state of India

D. C. Gautam[1], Meena Kumari[2]

[1]Himachal Pradesh University, Shimla, India, [2]Himachal Pradesh University, Shimla, India

Apple is an important fruit crop of Himachal Pradesh state of India. Green apple aphid, Aphis pomi De Geer and woolly apple aphid, Eriosoma lanigerum (Hausmann) are considered as the serious pests damaging the apple plants severely in all the apple growing regions of this state. Survey of the apple nurseries as well as apple orchards of this region revealed that the populations of Aphis pomi occurring on apple nursery plants are kept under control by a number of predators belonging to Coccinellidae and Syrphidae. The larvae and adult coccinnellid predators observed feeding on Aphis pomi populations in Himachal Pradesh are Cheilomenes sexmaculata (F.), Coelophora bissellata Mulsant, Coelophora saucia (Mulsant) and Harmonia dimidiata (F.) and the syrphid larvae recorded feeding on green apple aphid are Betasyrphus serarius (Weidemann), Episyrphus balteatus De Geer and Metasyrphus confrater (Weidmann). The biology and feeding potential of these prerdators of Aphis pomi, have been investigated in detail and are presented in this paper. The observations on the biological control of woolly apple aphid are still in progress. The present paper includes the detailed information on the various aspects of life history of these two aphid pests of apple in Himachal Pradesh, India and also on the biology and feeding potential of predators of Aphis pomi on apple nursery plants in this region. The findings may prove useful in developing the effective strategies for the management of these aphid pests in this region.

Phytosanitary risk of bruchids in import of legume germplasm in India

Shashi Bhalla[1], Manju Lata Kapur[2], Kavita Gupta[3], Charan Singh[4], Prakash Chandra Agarwal[5]

[1]National Bureau of Plant Genetic Resources, New Delhi, India, [2]National Bureau of Plant Genetic Resources, New Delhi, India, [3]National Bureau of Plant Genetic Resources, New Delhi, India, [4]National Bureau of Plant Genetic Resources, New Delhi, India, [5]National Bureau of Plant Genetic Resources, New Delhi, India

Import of legume germplasm for crop improvement is associated with quarantine risk of exotic bruchids which move across the countries as hidden infestation in seed. Import of planting material in India is regulated under Plant Quarantine (Regulation of Import into India) Order 2003 and National Bureau of Plant Genetic Resources is the nodal organization authorized to issue Import Permit for germplasm including transgenics meant for research and undertake their quarantine processing. The import of 140 legume genera germplasm carries the phytosanitary risk of over 500 bruchids into India. The quarantine risk is much higher due to their high economic significance, wide host range, adaptability and possibility of presence of biotypes in some bruchids. During last 35 years, ~70,000 imported samples of legumes were subjected to soft X rays generated generally at ~22Kv, 3 mA at a distance of 30 cm from the source for 30 seconds to detect and exclude hidden infestation. This resulted in detection of bruchid infestation in 5,823 samples representing 33 species of bruchids including 25 alien ones infesting > 35 legumes. Some of the bruchids intercepted from different countries but not yet reported from India included Bruchidius atrolineatus in Vigna unguiculata; Bruchus dentipes in Vicia faba; B. ervi in Lens spp., Lathyrus latifolius, Vicia spp.; Callosobruchus subinotatus in Voandzeia subterranea; Merobruchus paquetae in Albizia guachepele; Mimosests mimosae and M. nubigens in Acacia farnesiana. Phytosanitary risk assessment and mitigation measures are therefore extremely important to facilitate safe import of plants and planting material for agricultural biosecurity.

Effects of gamma radiation on mature larvae of *Pectinophora gossypiella* (Saunders) and their F1 progeny

Syed Shahzad Ali

Sindh Agriculture University Tandojam, Pakistan

The mature larvae of Pectonophora gossypiella (Saunders) obtained from the laboratory culture maintained on casein wheat germ diet were irradiated at 35, 45, 55 and 65 Gy doses at a dose rate of 30.8 Gy/min. in a Cs-137 gamma irradiator. The pupation was delayed as the radiation dose increased. Furthermore, larval survival to pupal and adult stages were also susceptible to gamma radiation doses were increased. Females were more susceptible to gamma radiation than males. The effect of gamma radiation on reproduction in P1 months following irridation of mature larvae was dose dependent. As the dose of mature larvae increased, average egg production, hatch percentage and adult longevity reduced. Egg production, was reduced more drastically in the crosses Untreated Male x Treated Female (UTM x TF) and Treated male x Treated Female (TM X TF) than the crosses Treated Male x Untreated Female (TM x UTF). Complete sterility was recorded when treated males were paired with treated females at 45 Gy and higher doses of gamma radiation. The results on the egg production, hatch percentage and adult longevity of F1 progeny of male parents following irridation of mature larvae showed that egg production was reduced significantly in crosses UTM x F1 Female at 35 Gy and complete sterility was recorded at higher doses. In crosses F1 Male x F1 Female, complete sterility was recorded at all the test doses of gamma radiation. The radiation doses higher than 35 Gy were more lethal either in F1 Male x F1 Female.

Effect of different temperature regimes on the development of *Bracon hebetor* (Say) (Hymenoptera: Braconidae) and its parasitism

Rashad Rasool Khan[1], Muhammad Ashfaq[2], Sohail Ahmed[3], Khuram Zia[4], Muhammad Arshad[5], Muhammad Dildar Gogi[6]

[1]University of Agriculture, Pakistan, [2]University of Agriculture, Pakistan, [3]University of Agriculture, Pakistan, [4]University of Agriculture, Pakistan, [5]University of Agriculture, Pakistan, [6]University of Agriculture, Pakistan

The parasitizing ability and biology of a larval parasitoid; Bracon hebetor (Say) (Hymenoptera: Braconidae) were studied in an experiment to determine the optimum conditions for its mass rearing. It was observed in this experiment, that the host larvae were completely parasitized, by the parasitoid, at 25 ± 2 °C and 30 ± 2 °C of temperatures. However, at higher temperatures the parasitism as well as the growth of the parasitoid, were negatively affected. So it is concluded that the best ecological conditions, for the mass rearing of the parasitoid as well as its performance are 30 ± 2 °C of temperature, 65 ± 10 % R.H and 16:8 L:D, periods.

Behavior of inscet-pests and pathogens on the cones and seeds of *Pinus gerardiana* (Chilgozapine)

Pawan Kumar
Himalayan Forest Research Institute (ICFRE), Shimla, India

Pawan Kumar, RC Sharma and VRR Singh Abstract: Pinus gerardiana Wall. 1832, commonly called as Chilgoza pine, mostly grows in valleys at 2000-3350 m, amsl elevation, in the dry temperate forest of the inner ranges of the Himalaya, where the summer monsoon is weak and precipitation, mostly in the form of snow, rarely exceeds 1000 mm per year. Insects constitute one of major biological destructive agents in tree seed productivity. The export of Chilgoza seeds contributes appreciably to the annual income of the most of the families living in the areas of its distribution. In the district of Kinnaur (Himachal Pradesh) alone, the approximate value of export of its annual produce is around 18 Crore of rupees in a year. But the cone and seeds are now being attacked by variety of insect-pests and pathogens causing degradation in the quality of seeds and even loss of seed crop. Cones and seeds of coniferous tree species are heavily attacked by coneworms, Dioryctria abietella and Cateremna (Euzophera) cedrella (Lepidoptera: Pyralidae) in western Himalaya. Dioryctria abietella is responsible for causing economic losses in cones and seeds of various conifer species. In Chilgoja pine, reported almost 100% attack at Kalpa, Himachal Pradesh. Insect damage varies greatly, depending on age, tree species, location, and insect control plan. On occasion, orchards may lose their entire seed crop. Without seed, there can be no seedlings, and without pest management expertise, seed crops are at risk to damage or destruction caused by insects and diseases. Such damage could

Isolation and identification of Alfalfa mosaic virus from Egypt

Sahar Hassan El Helaly[1], Amin Abo El-Ghar[2], Awad Mohamed Ahmed[3], Amal Farghaly[4]

[1]Menofia University, Egypt, [2]Menofia University, Egypt, [3]Menofia University, Egypt, [4]Menofia University, Egypt

Egypt is the most important of Mediterranean countries produced potato crop. Alfalfa mosaic virus is one of the most important viruses that infect potato. The aim of this study is: virus isolation from potato, virus identification using transmission methods, biological methods, serological methods, light microscope, electron microscope and molecular methods also measure the susceptibility of some local and imported verities and the effect of virus infection to some vegetative characters, physiological and chemical analysis of potato plants (chlorophyll, carbohydrates, protein, starch and mineral elements N,P and K).after isolation and identification we found that: Host range: Reaction to different hosts differed according to the host plant and virus isolate. Mode of transmission: Isolated virus was readily transmitted mechanically Insect transmission differed according to the species of aphid AMV easily transmitted by grafting Serological studies: Infected plants gave positive reaction with AMV antiserum Viral infection caused anatomical changes of infected tobacco plants using light and electron microscopy. All of local and imported cultivars were susceptible to the virus. AMV infection affect some of vegetative characters, photosynthetic pigments and chemical constituents. Finally the molecular characterization of the viral genome of the Egyptian isolates.
